Proposed interface for Standard ML Stream I/O

Andrew W. Appel
January 11, 1995

1 Introduction

The Input/Output interface provides:

- buffered reading and writing;
- arbitrary lookahead, using an underlying “lazy streams” mechanism;
- dynamic redirection of input or output;
- random access;
- uniform interface to text and binary data;
- layering of stream translations, through an underlying “reader/writer” interface;
- unbuffered input/output, through the reader/writer interface or even through the buffered stream interface;
- primitives sufficient to construct facilities for random access reading/writing to the same file.

In addition, the prescriptions and recommendations herein allow for efficient implementation, minimizing system calls and memory-memory copying.

The I/O system has several layers of interface. From bottom to top, they are

PRIM.IO Uniform interface for unbuffered reading and writing at the “system call” level, though not necessarily via actual system calls.

STREAM.IO Buffered “lazy functional stream” input; buffered conventional output.

IO Buffered, conventional (side-effecting) input and output with redirection facility.

Because most programmers will use the IO interface, I will describe that first, rather informally. Then I will go bottom-up over the entire system, giving a technical specification of the interfaces, and their axioms and pragmatics.1

1All footnotes in this document indicate unresolved issues. Issues should be resolved, and footnotes removed, by the last draft.
2The conventions for multi-word identifiers (underscores vs. capitalization) in the initial basis are still unresolved. Therefore, I have been inconsistent in my punctuation.
2 IO

Conventional buffered input/output is done using several structures matching the IO signature: TextIO, for character input/output, BinIO, for binary (byte) input/output.³

signature IO =
  sig
  type instream
  type outstream
  type elem
  type vector
  type pos

  val open_in : string -> instream
  val close_in : instream -> unit
  val input : instream -> vector
  val input_all : instream -> vector
  val input_noblock : instream -> vector option
  val input1 : instream -> elem option
  val input_n : instream * int -> vector
  val end_of_stream : instream -> bool
  val lookahead : instream -> elem option
  val setpos_in : instream * pos -> unit
  val getpos_in : instream -> pos
  val endpos_in : instream -> pos

  val open_out : string -> outstream
  val close_out : outstream -> unit
  val output : (outstream * vector) -> unit
  val output1 : outstream * elem -> unit
  val flush_out : outstream -> unit
  val getpos_out : outstream -> pos
  val endpos_out : outstream -> pos
  val setpos_out : outstream * pos -> unit

structure StreamIO : STREAM_IO
sharing type elem = StreamIO.elem
sharing type vector = StreamIO.vector
sharing type pos = StreamIO.pos

val mk_instream : StreamIO.instream -> instream
val get_instream : instream -> StreamIO.instream
val set_instream : instream * StreamIO.instream -> unit

val mk_outstream : StreamIO.outstream -> outstream
val get_outstream : outstream -> StreamIO.outstream

³Perhaps it would be better to separate input and output in the the IO modules and signatures. There seems to be no reason not to do this, except that it means twice as many modules.
val set_outstream : outstream * StreamIO.outstream -> unit
end

structure FilePosInt : INTEGER

signature BIN_IO =
sig
  include IO
  sharing type pos=FilePosInt.int
  sharing type StreamIO.elem=Word8.word
  sharing type StreamIO.vector=Word8Vector.vector
end

structure BinIO : BIN_IO

signature TEXT_IO =
sig
  include IO
  sharing type StreamIO.elem = char
  sharing type StreamIO.vector = string
  sharing type pos=FilePosInt.int
  val std_in : instream
  val std_out : outstream
  val std_err : outstream
  val translate_in : BinIO.StreamIO.PrimIO.reader ->
    TextIO.StreamIO.PrimIO.reader
  val translate_out : BinIO.StreamIO.PrimIO.writer ->
    TextIO.StreamIO.PrimIO.writer
end

structure TextIO : TEXT_IO

Operations on instreams

elem
   A single element (member of a stream); for TextIO streams this is char; for BinIO
   this is Word8.word.

vector
   A sequence of elements (such as string or Word8Vector.vector).

  \[ f = \text{open\_in}(s) \]
  Opens a file named \( s \) as a stream \( f \).

\footnote{The BinIO and TextIO modules, as well as all their substructures, provide general operations on
streams, no matter how these streams are opened. Thus, they are almost entirely operating-system indepen-
dent. Putting open\_in and open\_out in these modules introduces an operating-system dependency. It is
intended that users or vendors may provide some structure \( X \) matching the IO signature; such a structure
may not want to provide any open\_in of this form (taking a string argument). In that case, \( X\text{.open\_in} \)
close_in(f)
Close f; no further operations are permitted on f (they will raise the Io exception).

v = input(f)
Read some elements of f, returning a vector v. If (and only if) f is at end of file, size(v) = 0. May block (not return until data is available in the external world).

v = input_all(f)
Return the vector v of all the elements of f up to end of stream.

input_noblock(f)
If any elements of f can be read without blocking, return at least one of them. If it is possible to determine without blocking that f is at end of stream, return some(empty). Otherwise return none.

c = input1(f)
If at least one element e of f is available, return some(e). If f is at end of file, return none. Otherwise block until one of those conditions occurs.

v = input_n(f,n)
If at least n elements remain before end of stream, return the first n elements. Otherwise, return the (possibly empty) sequence of elements remaining before end of stream. Blocks if necessary. (This was the behavior of the input function in the 1989 Definition of Standard ML, and pre-1.00 releases of SML/NJ.)

end_of_stream(f)
False if any elements are available in f; true if f is at end of stream. Otherwise blocks until one of these conditions occurs. Exactly equivalent to (size(input f)=0).

c = lookahead(f)
Return the next element without advancing the stream; or at end of file return none. Multiple-character lookahead can be accomplished with the lazy functional stream interface; see section 6.

setpos_in(f,i)
Seek to position i in f. Not always supported (raises Io if not supported on f).

i = getpos_in(f)
Tell the current position of f. For the standard modules TextIO and BinIO, i is an integer equal to the number of elements since the beginning of the file. Positions correspond 1–1 to elements in the file, and are not in any way abstract. Not always supported (raises Io if not supported on f).

i = endpos_in(f)
Tell the ending position of f. For the standard modules TextIO and BinIO, i is an integer equal to the number of elements in the file. Not always supported (raises Io if not supported on f).

should raise an exception. This is slightly inelegant; Berry and Reppy would like to see open_in removed from the IO signature and put in an operating-system dependent structure such as OS.File. I put the functions in IO for users’ convenience, but I could be convinced to remove them.
Operations on outstreams

\[ f = \text{open\_out}(s) \]
Open (for writing) a file named \( s \) (creating it if necessary) as an outstream \( f \).

\[ \text{close\_out}(f) \]
Flush \( f \)'s buffer and close the stream (releasing operating-system resources associated with it).

\[ \text{output}(f, v) \]
Write the sequence \( v \) to \( f \).

\[ \text{output1}(f, x) \]
Write the element \( x \) to \( f \).

\[ \text{flush\_out}(f) \]
Flush \( f \)'s buffer: that is, make the underlying file reflect any previous \text{output} operations.

\[ i = \text{getpos\_out}(f) \]
Tell the current position of \( f \) (\textit{not always supported}).

\[ i = \text{endpos\_out}(f) \]
Tell the ending position of \( f \) (\textit{not always supported}). For the standard modules \texttt{TextIO} and \texttt{BinIO}, \( i \) is an integer equal to the number of elements in the file. \textit{Not always supported} (raises \texttt{Io} if not supported on \( f \)).

\[ \text{setpos\_out}(f, i) \]
Seek to position \( i \) of \( f \) (\textit{not always supported}). For the standard modules \texttt{TextIO} and \texttt{BinIO}, \( i \) is an integer equal to the number of elements since the beginning of the file. Positions correspond 1–1 to elements in the file, and are not in any way abstract.

Any of these functions may raise the \texttt{Io} exception if an operation fails (including \text{close\_out} if a buffer cannot be flushed).

Random access

The \texttt{getpos}, \texttt{endpos}, \texttt{setpos} functions all operate on special \texttt{FilePosInt} integers. In some implementations these may be ordinary integers, in others they may be double-precision or even arbitrary precision integers. Thus, one of the following might be true:

\begin{align*}
\text{structure FilePosInt} &= \text{Int} \\
\text{or structure FilePosInt} &= \text{Int64} \\
\text{or structure FilePosInt} &= \text{LargeInt}
\end{align*}

\texttt{FilePosInt} might be some other integer structure. This allows operations on extremely large files.

Users can operate on the \texttt{pos} type using \texttt{FilePosInt.+} and \texttt{FilePosInt.-}; or convert to/from ordinary integers using \texttt{FilePosInt.toDefault} and \texttt{FilePosInt.fromDefault}—at the risk of being unable to process large files.\footnote{Perhaps we should require that \texttt{FilePosInt} be abstract; that is, abstraction \texttt{FilePosInt : INTEGER = Int}, so that programmers are forced to write more portable code.}

\[5\]
Closing files on program exit

All streams created by TextIO.open_in, TextIO.open_out, BinIO.open_in, and BinIO.open_out
will be closed (the outstreams among them flushed) when the ML program exits. The out-
streams std_out and std_err will be flushed, but not closed, on program exit.

Redirecting IO streams

There is also a set of primitives to relate IO streams to the “lazy functional streams” model
of input/output; and thus to the underlying unbuffered reader/writer primitives:

StreamIO

The particular instantiation of the STREAM_IO interface underlying this IO mod-
ule (i.e., streams of bytes, chars, or some other element type).

\[ f = \text{mk_instream}(s) \]

Create a conventional stream \( f \) from a functional stream \( s \).

\[ s = \text{get_instream}(f) \]

Extract the functional stream \( s \) from \( f \). This allows arbitrary lookahead; for example:

\[
\text{fun \ lookahead\_n/(f/,n/) =} \\\n  \text{let val } f' = \text{mk\_instream(get\_instream(f))} \\\n  \text{in input\_n(f',n)} \\\n  \text{end}
\]

This makes a “copy” \( f' \) of the stream \( f \); then input operations in \( f' \) won’t affect \( f \)
(though setpos_in on \( f' \) may effectively close \( f \)). For more details, see sections 4, 5,
6, 7, and 8, which give a more precise specification of stream behavior.

\[ \text{set\_instream}(f, s) \]

Redirect \( f \), so that further input comes from \( s \). For example:

\[
\text{fun \ from\_file/(g/,name/) =} \\\n  \text{let val } f = \text{open\_in name} \\\n  \text{val save\_std\_in = get\_instream std\_in} \\\n  \text{in set\_instream(std\_in, get\_instream f);} \\\n  \text{g();} \\\n  \text{set\_instream(std\_in, save\_std\_in)} \\\n  \text{end}
\]

For more details, see the next few sections.

\[ f = \text{mk\_outstream}(s) \]

Create a conventional outstream \( f \) from a StreamIO.outstream \( s \). The output
streams in StreamIO are not “functional,” they are conventional streams operated on by side-effecting output. The difference between an IO.outstream and a StreamIO.outstream is that the former may be redirected using set.outstream. Think of the former as a ref of the latter.
\[ s = \text{get\_outstream}(f) \]

Extract the underlying outstream \( s \) from the redirectable outstream \( f \). Unfortunately, \( s \) is not "pure functional," so there's no equivalent of the lookahead trick shown above. Unlike instreams, if

\[ \text{val } f' = \text{mk\_outstream}(\text{get\_outstream } f) \]

then operations on \( f' \) are equivalent to operations on \( f \).

\[ \text{set\_outstream}(f, s) \]

Useful for redirecting output. For example,

\[ \text{fun to\_file}(g, \text{name}) = \]
\[ \quad \text{let val } f = \text{open\_out } \text{name} \]
\[ \quad \quad \text{val save\_std\_out = get\_outstream } \text{std\_out} \]
\[ \quad \quad \text{in set\_outstream}(\text{std\_out}, \text{get\_outstream } f); \]
\[ \quad \quad g(); \]
\[ \quad \text{set\_outstream}(\text{std\_out}, \text{save\_std\_out}) \]
\[ \quad \text{end} \]

In can be argued that this is not very elegant; the function \( g \), instead of writing stuff to \textit{std\_out}, should have been parameterized (in the usual ML way) on an \textit{outstream} from the very beginning. Then the \textit{get} and \textit{set} primitives wouldn't be needed.

**Translation**

In some environments, the external representation of a text file is different from its internal representation: for example, in MS-DOS, text files on disk contain CR-LF, and in memory contain only LF at the end of each line. Binary streams (\textit{BinIO.instream}) match the external files byte for byte; text streams (\textit{TextIO.instream}) are translated. Normally, users of \textit{TextIO} will not need to know or care about this translation; but for more sophisticated users, the translation functions are made visible as \textit{TextIO.translate\_in} and \textit{TextIO.translate\_out}. On Unix systems, these will be identity functions. See section 9.4.

### 3 OS

The primitive I/O (\textit{PrimIO}), stream I/O (\textit{StreamIO}), and standard I/O (\textit{IO}) packages require only these components of the OS structure:

\[ \text{structure OS : sig} \]
\[ \quad \text{type syserror} \]
\[ \quad \text{val noError} : \text{syserror} \]
\[ \quad \text{exception SysErr of} \]
\[ \quad \quad \{ \text{ml\_op : string,} \]
\[ \quad \quad \quad \text{os\_op : string,} \]
\[ \quad \quad \quad \text{reason : syserror} \} \]

\[ \quad \text{end} \]
For basic "operating system" functions such as reading and writing, the input/output modules do not reference the OS structure directly. Instead, each stream is built on a PrimIO.reader or PrimIO.writer; the readers and writers contain functions that can accomplish the system calls. But it is also possible for users to synthesize readers or writers that don't do system calls at all, or do unconventional ones. The parameterization of IO on "readers" and "writers" is described in the next section.

4 PRIM_IO

Primitive I/O is meant to be an abstraction of the system call operations commonly available on file descriptors. 6

signature PRIM_IO =
  sig
    type elem
    type vector
    type array
    type pos

    exception Io of {
      ml_op : string,
      name : string,
      os_op : string,
      reason : string,
      syserror : OS.syserror
    }

  datatype reader = Rd of {
    read_noblock : (int -> vector option) option,
    reada_noblock: ({data: array, first: int, nelems: int} -> int option) option,
    read_block : (int -> vector) option,
    reada_block: ({data: array, first: int, nelems: int} -> int) option,
    block : (unit -> unit) option,
    can_input : (unit -> bool) option,
    name : string,
    chunksize : int,
    close : unit -> unit,
    getpos : (unit -> pos) option,
    setpos : (pos -> unit) option,
    endpos : (unit -> pos) option,
    find_pos : ({data: vector, first: int, nelems: int} * pos -> pos)) option
  }

  datatype writer = Wr of

  [6] Perhaps Io shouldn't be in this signature; where should it live?
A file (device, etc.) is a sequence of "elements" (elem), which may (for example) be characters or bytes. The distinction between characters and bytes is necessary on DOS, where CR-LF is translated to LF when reading character files; or on Windows-NT where characters are 16-bits (Unicode) and bytes are 8 bits.

One typically reads or writes a sequence of elements in one system call: this sequence is the vector type. Sometimes it is useful to write the sequence from a mutable array instead of from the vector.

A reader is a file (device, etc.) opened for reading, and a writer one opened for writing. The components of a reader are

**close()**

Closes the reader (for example, frees operating system resources). Further operations to this reader are illegal and must be checked for by the reader (the Io exception must be raised).

**name**

The name associated with this file or device, for use in error messages shown to the user.

**chunksize**

The recommended (efficient) size of read operations on this reader. This is typically to the block size of the operating system's buffers. If that is not known, a value of 2048 or 4096 will probably work well. **Chunksize = 1** strongly recommends (but cannot guarantee, since buffering occurs in other modules, not this one) unbuffered I/O on this reader. **Chunksize = 0** is illegal.
\texttt{read\_noblock}(n)  
(optional) Reads \(i\) elements without blocking, for \(0 < i \leq n\) creating a vector \(v\), returning \texttt{some}(v); or (if a read would block) returns \texttt{none}.

\texttt{read\_block}(n)  
(optional) Reads \(i\) elements for \(0 < i \leq n\) returning a vector \(v\) of length \(i\); blocks (waits) if necessary until at least one element is available.

\texttt{reada\_noblock}\{\texttt{buf}=a,\texttt{first}=i,\texttt{nelems}=n\}  
(optional) Reads \(k\) elements without blocking, for \(0 < k \leq n\) into \(a_i, \ldots, a_{i+k-1}\), returning \texttt{some}(k); if no elements remain before end-of-file, returns \texttt{some}(0) without blocking; or (if a read would block) returns \texttt{none}.

\texttt{reada\_block}\{\texttt{buf}=a,\texttt{first}=i,\texttt{nelems}=n\}  
(optional) Reads \(k\) elements for \(0 < k \leq n\) into \(a_i, \ldots, a_{i+k-1}\), returning a vector \(k\); blocks (waits) if necessary until at least one element is available. If no elements remain before end-of-file, returns 0.

\texttt{block}()  
(optional) Returns only when at least one element is available for read without blocking.

\texttt{can\_input}()  
(optional) Returns \texttt{true} iff the next read can proceed without blocking.

\texttt{getpos}()  
(optional) Tells the current position in the file. Useful even for non-seeckable files, if the \texttt{endpos} function is provided (because large input operations are more efficient if the distance from “here to end of file” is known).

\texttt{setpos}(i)  
(optional) Move to position \(i\) in file.

\texttt{endpos}()  
(optional) The position at the end of the file.

\texttt{find\_pos}\{\texttt{data}=v,\texttt{first}=i,\texttt{nelems}=n,\texttt{p}\}  
(option) If \texttt{find\_pos=none}, then positions in the reader must correspond 1-1 to elements returned from the \texttt{read} functions; and \texttt{endpos} returns exactly the number of elements in the file. If \texttt{find\_pos=some}(f), then this is not necessarily true. In that case, \(f(\texttt{data}=v,\texttt{first}=i,\texttt{nelems}=n,\texttt{p})\) tells the position of the \((i+n)\)th element of the vector \(v\), assuming that the position of the \(i\)th element is \(p\). Section 9.4 explains why this is useful.

One of \texttt{read\_block}, \texttt{reada\_block}, \texttt{read\_noblock}, or \texttt{reada\_noblock} must be provided.

Providing more of the optional functions increases functionality and/or efficiency of clients:

1. Absence of all of \texttt{read\_block}, \texttt{reada\_block}, and \texttt{block} means that blocking input is not possible.
2. Absence of all of `read_noblock`, `reada_noblock`, and `can_input` means that non-blocking input is not possible.

3. Absence of `read_noblock` means that non-blocking input requires two system calls (using `can_input`, `read_block`).

4. Absence of `reada_noblock` or `reada_block` means that input into an array requires extra copying. But I do not anticipate that reading into arrays will normally be very important in the "lazy functional stream" model.

Clients of PrimIO are required to synthesize blocking reads from `read_noblock+block`, synthesize vector reads from array reads, synthesize array reads from vector reads, as needed—so the PrimIO.reader is required to provide only a minimum set. If the reader can provide more than the minimum set in a way that is more efficient than the obvious synthesis than by all means it should do so. Providing more than the minimum by just doing the obvious synthesis inside the PrimIO layer is not recommended because then clients won't get the "hint" about which are the efficient ("recommended") operations.

The augment_in function takes a reader \( r \) and produces a reader in which as many as possible of `read_block`, `reada_block`, `read_noblock`, `reada_noblock` are provided, by synthesizing these from the operations of \( r \).

5. Absence of `endpos` means that very large inputs (where vectors must be pre-allocated) cannot be done efficiently (in one system call, without copying).

6. Absence of `getpos`, in the unusual case where a buffered system is applied to a reader not positioned at the beginning of the file, may lead to excessive memory allocation of vectors for very large input operations.

7. Absence of `getpos` means that buffered `setpos` may be less efficient.

8. Absence of `setpos` prevents random access.

9. If `getpos` is provided, and `pos` positions do not correspond 1-1 to elements returned from the `read` functions, then `find_pos` must be provided. This will typically be necessary when the reader is performing some sort of translation on the input stream. If the translation function is invertible, then `find_pos` will be straightforward to implement. If not invertible, then `find_pos` can seek to `pos` in the underlying file, and re-translate forward to the right point. In that case, the implementation of `find_pos` will probably require: \( p_0 = \text{getpos}, \text{setpos}(pos), \text{read}, \text{setpos}(p_0) \) to restore the file position to what it was before the `find_pos` operation.

10. If `find_pos` is `some(f)`, then clients of this reader will probably do many `getpos` operations. For efficiency, if `find_pos=\text{some}(f)`, the reader should keep track of file positions, incrementing with each `read`, so as to avoid a system call for each `getpos` operation.

11. Even when `find_pos=\text{none}`, the reader could keep track of file positions to avoid system calls for `getpos`. It may be the case, however, that the vast majority of files are read only sequentially, so it may not be useful to optimize `getpos`.

The components of a writer are:
write
block{buf=v,first=i,nelems=n}
This (optional) function writes elements $v_i, \ldots, v_{i+k-1}$, for $k \leq n$ to the output device, and returns some($k$); or (if the write would block) returns none. $k = 0$ is not recommended (prohibited?). Raises Io on failure of underlying system call, or Subscript if $i < 0$ or $i+n > length(v)$.

write
noblock{buf=a,first=i,nelems=n}
This (optional) function without blocking writes elements $a_i, \ldots, a_{i+k-1}$, for $k \leq n$ to the output device, and returns some($k$); or (if the write would block) returns none. $k = 0$ is not recommended (prohibited?).

write
block{buf=v,first=i,nelems=n}
This (optional) function writes elements $v_i, \ldots, v_{i+k-1}$, for $0 < k \leq n$ to the output device, and returns $k$. If necessary, waits (blocks) until the external world can accept at least one element.

write
noblock{buf=a,first=i,nelems=n}
This (optional) function writes elements $a_i, \ldots, a_{i+k-1}$, for $0 < k \leq n$ to the output device, and returns $k$. If necessary, waits (blocks) until the external world can accept at least one element.

write
block{buf=v,first=i,nelems=n}
This (optional) function writes elements $v_i, \ldots, v_{i+k-1}$, for $0 < k \leq n$ to the output device without blocking, and returns some($k$); or (if the write would block) returns none.

write
noblock{buf=a,first=i,nelems=n}
This (optional) function writes elements $a_i, \ldots, a_{i+k-1}$, for $0 < k \leq n$ to the output device without blocking, and returns some($k$); or (if the write would block) returns none.

block()
This (optional) function does not return until the writer is guaranteed to be able to write without blocking.

can output()
(optional) Returns true iff the next write can proceed without blocking.

name
The name associated with this file or device, for use in error messages shown to the user.

chunksize
The recommended (efficient) size of write operations on this writer. This is typically to the block size of the operating system's buffers. If that is not known, a value of 2048 or 4096 will probably work well. Chunksize = 1 strongly recommends (but cannot guarantee, since buffering occurs in other modules, not this one) unbuffered I/O on the writer. Chunksize $\leq 0$ is illegal (functions in other modules taking writers as arguments may raise exceptions).

close()
Closes the writer (for example, frees operating system resources devoted to this
Further operations to this writer are illegal and must be checked for by
the writer (Io must be raised).

getpos()
   (optional) Tells the current position within the file. Most useful on seekable writers.

endpos()
   (optional) The position at the end of the file.

setpos(i)
   (optional) Moves to position i in the file, so future writes occur at this position.

One of write_block, writea_block, write_noblock, or writea_noblock must be pro-
vided. Providing more of the optional functions increases functionality and/or efficiency of
clients:

1. Absence of all of write_block, writea_block, and block means that blocking output
   is not possible.

2. Absence of all of write_noblock, writea_noblock, and can_output means that
   non-blocking output is not possible.

3. Absence of write_noblock means that non-blocking output requires two system calls
   (using can_output, write_block).

4. Absence of writea_block or writea_noblock means that extra copying will be re-
   quired to write from an array.

5. Absence of writea_noblock, write_noblock, and can_output from a writer means
   that nonblocking output is impossible. But the standard StreamIO modules do not
   support nonblocking output anyway.

6. Absence of getpos means that buffered setpos may be less efficient.

7. If pos \neq int then buffered setpos may be difficult to implement; but for “standard”
   modules pos=int

8. Absence of setpos prevents random access.

The augment_out function takes a writer w and produces a writer in which as many as
possible of write_block, writea_block, write_noblock, writea_noblock are provided,
by synthesizing these from the operations of w.

Any of the component functions of readers or writers may raise the Io exception. No
other exceptions should be raised. The components of Io are:

ml_op
   The name of the reader/writer component function raising the exception.

name
   Should equal the name component of the reader or writer.

os_op
   The name of the operating system call (if any) that failed, otherwise empty.
If the Io exception is raised as the result of handling an OS.SysErr exception, then the reason code provided by the operating system. Otherwise, OS.noError.

reason
If syserror ≠ OS.noError, then OS.errorName(syserror); otherwise, a textual summary of the error.

The functions open_in and open_out provide system-default ways to create readers from “file names.” Structures matching this signature may leave these two functions unimplemented (by having them raise the Io exception) if there is no appropriate system default.

5 PrimIO

The functorPrimIO builds standard instances of the PRIM_IO signature.

functor PrimIO(structure A : MONO_ARRAY
structure V : MONO_VECTOR
sharing type A.elem=V.elem
val someElem : A.elem
structure Pos : INTEGER) : PRIM_IO =
struct ... end

The only non-trivial parts of the PrimIO functor are the implementations of the functions augment_in, and augment_out, etc. simulate one kind of reader (or writer) functionality in terms of other kinds. For example:

fun augment_in (r as Rd r') =
let reada_to_read reada i =
  let val a = A.array(i,someElem)
    val i' = f{data=a,first=0,nelems=i};
  in A.extract(a,0,i')
end

val read_block' =
case r
  of Rd{read_block=SOME f,...} => SOME f
   | Rd{reada_block=SOME f,...} => SOME(reada_to_read f)
   | Rd{read_noblock=SOME f,block=SOME b,...} =>
      SOME(fn i => (b(); f i))
   | Rd{reada_noblock=SOME f, block=SOME b,...} =>
      SOME(fn i => (b(); reada_to_read f i))
   | _ => NONE

  ... in Rd{block= #block r', ... read_block=read_block', ... }
end

6 STREAM_IO

The Stream I/O interface provides buffered reading and writing to input and output streams.
Input streams are treated in the lazy functional style: that is, input from a stream \( f \) yields a finite vector of elements, plus a new stream \( f' \). Input from \( f \) again will yield the same elements; to advance within the stream in the usual way it is necessary to do further input from \( f' \). This interface allows arbitrary lookahead to be done very cleanly, which should be useful both for \textit{ad hoc} lexical analysis and for table-driven, regular-expression-based lexing.

Output streams are handled more conventionally, since the lazy functional style doesn’t seem to make sense for output.

signature STREAM_I0 =

sig
structure PrimIO: PRIM_I0

    type elem sharing type elem = PrimIO.elem
    type vector sharing type vector = PrimIO.vector
    type pos sharing type pos = PrimIO.pos

type instream

type outstream

val open_in : string -> instream
val mk_instream : PrimIO.reader -> instream
val close_in : instream -> unit
val setpos_in : instream * pos -> instream
val getpos_in : instream -> pos
val endpos_in : instream -> pos
val input : instream -> vector * instream
val input_all : instream -> vector
val input_noblock : instream -> (vector * instream) option
val input1 : instream -> elem option * instream
val input_n : instream * int -> vector * instream
val end_of_stream : instream -> bool
val get_reader : instream -> PrimIO.reader

val open_out : string -> outstream
val mk_outstream : PrimIO.writer -> outstream
val close_out : outstream -> unit
val output : (outstream * vector) -> unit
val output1 : (outstream * elem) -> unit
val flush_out : outstream -> unit
val getpos_out : outstream -> pos
val setpos_out : outstream * pos -> unit
val endpos_out : outstream -> pos
val get_writer : outstream -> PrimIO.writer

end

Each instream \( f \) can be viewed as a sequence of “available” elements (the buffer or sequence of buffers) and a mechanism (the \texttt{reader}) for obtaining more. After an opera-
tion \((v, f') = \text{input}(f)\) it is guaranteed that \(v\) is a prefix of the available elements. In a “truncated” instream, there is no mechanism for obtaining more, so the “available” elements comprise the entire stream. In a “terminated” outstream, there is no mechanism for outputting more, so any output operations will raise the \(\text{Io}\) exception.

**PrimIO**

Every instance of \(\text{STREAM.IO}\) is built over an instance of \(\text{PRIM.IO}\).

elem

A single element (member of a stream).

vector

A sequence of elements, just as in \(\text{PRIM.IO}\).

\(f = \text{open_in}(s)\)

Opens a file named \(s\) as a stream. “Default” implementations of \(\text{STREAM.IO}\) will support \(\text{open_in}\); other implementations may choose to support only \(\text{mk_instream}\), raising \(\text{Io}\) on \(\text{open_in}\).

\(f = \text{mk_instream}(r)\)

Create a buffered stream \(f\) from a reader \(r\). In \(r\), \text{read_block}, \text{reada_block}, and \text{block} must not all be \text{none} or an \(\text{Io}\) exception will be raised. (Most users will normally use \(\text{open_in}\) instead.)

\(\text{close_in}(f)\)

Truncate \(f\), and release operating system resources associated with the underlying file (if any).

\(g = \text{setpos_in}(f, i)\)

Now \(g\) is a new instream starting from position \(i\) of \(f\). \(f\) may or may not be truncated, depending on whether the \text{setpos} request can be satisfied within the buffer. (Nondeterministic behavior! is that bad?) \text{Not always supported}.

\(\text{getpos_in}(f)\)

Return the current position of \(f\). \text{Not always supported}.

\(\text{endpos_in}(f)\)

Return the position at end of file of \(f\). \text{Not always supported}.

\((v, f') = \text{input}(f)\)

If any elements of \(f\) are available, return sequence \(v\) of one or more elements and the “remainder” \(f'\) of the stream. If \(f\) is at end of file, return the empty sequence. Otherwise read from the operating system (which may block) until one of those conditions occurs.

\(v = \text{input_all}(f)\)

Return the vector \(v\) of all the elements of \(f\) up to end of stream. Semantically equivalent to:

\[
\text{fun input_all(f) = let val (a,f') = input f in if size(a)=0 then a else a ^ input_all f', end}
\]
where $\s$ is the concatenation operator on element vectors.

\[(v, f') = \text{input\_noblock}(f)\]

If any non-empty sequence $v$ of $f$ is available or can be read from the operating system without blocking, return $\text{SOME}(w, f')$ where $w$ is any non-empty prefix of $v$, and $f'$ is the “rest” of the stream. Otherwise return $\text{NONE}$.

\[(e, f') = \text{input1}(f)\]

If at least one element $e$ of $f$ is available, return $(\text{SOME}(e), f')$. If $f$ is at end of file, return the $\text{NONE}$. Otherwise read from the operating system (which may block) until one of those conditions occurs. Semantically equivalent to:

\[
\text{fun input1}(f) = \text{let val } (v,f') = \text{input } f \\
\quad \text{in } (\text{if size}(v)=0 \text{ then NONE else SOME}(\text{sub}(v,0)), \\
\quad \quad f') \\
\quad \text{end}
\]

\[(v, f') = \text{input\_n}(f,n)\]

If at least $n$ elements remain before end of stream, return the first $n$ elements. Otherwise, return the (possibly empty) sequence of elements remaining before end of stream. Blocks if necessary. (This was the behavior of the $\text{input}$ function in the 1989 $\text{Definition of Standard ML}$.) Semantically equivalent to:

\[
\text{fun input\_n}(f,0) = (\text{empty}, f) \\
\quad | \text{input\_n}(f,n) = \text{let val } (x,f') = \text{input1 } f \\
\quad \quad \quad \text{val } (s,f''') = \text{input\_n}(f,n-1) \\
\quad \quad \quad \text{in } (x^\s, f'''') \\
\quad \text{end}
\]

$\text{end\_of\_stream}(f)$

False if any characters are available in $f$; true if $f$ is at end of stream. Otherwise reads (perhaps blocking) until one of these conditions occurs. Exactly equivalent to $(\text{size}(\text{input } f)=0)$.

$\text{get\_reader}(f)$

Extract the underlying reader from $f$. Truncates $f$. Careful users should probably do something like

\[
\text{let val } r = \text{get\_reader } f \\
\quad \text{val } v = \text{input\_all } f \\
\quad \text{in } ... \\
\quad \text{end}
\]

so as to obtain the elements $v$ already in the buffer before doing anything with $r$.

$\text{f = open\_out}(s)$

Open (for writing) a file named $s$ (creating it if necessary) as an outstream $f$. Not always supported.
\( f = \text{mk\_outstream}(w, s) \)

Create a buffered outstream \( f \) from a writer \( w \). In \( w, \text{write\_block}, \text{write\_a\_block} \), and \text{block} must not all be \text{none} or an \text{Io} exception will be raised.

\[ \text{close\_out}(f) \]
Flush \( f \)'s buffer, terminate \( f \), then close the underlying writer (releasing operating-system resources associated with it).

\[ \text{flush\_out}(f) \]
Flush \( f \)'s buffer: that is, make the underlying file reflect any previous \text{output} operations.

\[ \text{output}(f, v) \]
Write the sequence \( v \) to \( f \); this may block until the system is prepared to accept more output. \text{StreamIO} does not provide any nonblocking output function.

\[ \text{output1}(f, x) \]
Write the element \( x \) to \( f \); may block.

\[ \text{get\_writer}(f) \]
Get the underlying writer associated with \( f \). Flushes and terminates \( f \).

\[ \text{getpos\_out}(f) \]
Give the current position of \( f \) in the underlying file. \text{Not always supported}.

\[ \text{endpos\_out}(f) \]
The position at the end of file \( f \). \text{Not always supported}.

\[ \text{setpos\_out}(f, i) \]
Set the current position of \( f \) in the underlying file to \( i \). Flush \( f \) if necessary. \text{Not always supported}.

Any prefix of the concatenation of previous writes (since the last \text{setpos} or \text{flush}) may be reflected in the underlying file.

Operations marked \text{Not always supported} may fail on some streams or in some instantiations of the STREAM\_IO signature, raising \text{Io\{syserror = OS.noError, \ldots\}}.\text{7}

Rules: The following expressions are all guaranteed \text{true}, if they complete without exception.

Input is semi-deterministic: \text{input} may read any number of elements from \( f \) the "first" time, but then it is committed to its choice, and must return the same number of elements on subsequent reads from the same point.

\[ \begin{align*}
\text{let val (a,\_)} &= \text{input } f \\
\text{val (b,\_)} &= \text{input } f \\
\text{in} &\quad a = b \\
\text{end}
\end{align*} \]

Closing a stream just causes the not-yet-determined part of the stream to be empty:

\text{Should we make a special \text{OS\_notSupported}?}
let val (a,f’) = input f 
  val _ = close_in f 
  val (b,_) = input f 
  in a=b andalso end_of_stream f’ 
end (* must be true *)

If a stream has already been at least partly determined, then input cannot possibly block:

let val a = input f 
  in case input_noblock f 
    of SOME a => a=b 
    | NONE => false 
  end (* must be true *)

Note that a successful `input_noblock` does not imply that more characters remain before end-of-file, just that reading won’t block.

A freshly opened stream is still undetermined (no “read” has yet been done on the underlying reader):

let val a = open_in name (* or,  a = mk_instream(r) *) 
  in close a; 
  size(input a) = 0 
end

This has the useful consequence that if one opens a stream, then extracts the underlying reader, the reader has not yet been advanced in its file.

Closing a stream guarantees that the underlying reader will never again be accessed; so input can’t possibly block:

(case (close f; input_noblock f) of SOME _ => true | NONE => false)

The `end_of_stream` test is equivalent to `input` returning an empty sequence:

let val (a,_) = input f in (size(a)=0) = (end_of_stream f) end

**Unbuffered I/O** That is, if chunksize=1 in the underlying reader, then `input` operations must be unbuffered:

let val f = mk_instream(reader) 
  val (a,f’) = input(f,n) 
  val PrimIO.Rd{chunksize,...}=get_instream f 
  in chunksize>1 orelse end_of_stream f’ 
end

Though `input` may perform a `read(k)` operation on the reader (for $k \geq 1$), it must immediately return all the elements it receives. However, this does not hold for partly determined instreams:

let val f = mk_instream(reader) 
  val _ = do_input_operations_on(f) 
  val (a,f’) = input(f,n) 
  val PrimIO.Rd{chunksize,...}=get_instream f 
  in chunksize>1 orelse end_of_stream f’ (* could be false*) 
end
because in this case, the stream \( f \) may have accumulated a history of several responses, and \texttt{input} is required to repeat them one at a time.

Similarly, output operations are unbuffered if \texttt{chunksize}=1 in the underlying writer. Unbuffered output means that the data has been written to the underlying writer by the time \texttt{output} returns.

\textbf{Don't bother the reader} \quad \texttt{input} must be done without any operation on the underlying reader, whenever it is possible to do so by using elements from the buffer. This is necessary so that repeated calls to \texttt{end_of_file} will not make repeated system calls.

This rule could be formalized by defining a "monitor:"

\begin{verbatim}
val monitor : reader -> {rd : reader,
   chars_read : int ref,
   op_count : int ref}
\end{verbatim}

and making statements such as:

\begin{verbatim}
let val \{rd,chars_read,op_count\} = monitor(reader)
val f = mk_instream(rd)
val (f',n_elems) = do_things_counting_elements(f)
val p1 = getpos_in f'
val c1 = !chars_read
val ops = !op_count
val _ = input f'
in not ((n_elem < c1) andalso (!op_count > ops))
\end{verbatim}

but perhaps this level of detail is unnecessary.

\textbf{Multiple end-of-file} \quad In Unix, and perhaps in other operating systems, there is no notion of "end of stream." Instead, by convention a \texttt{read} system call that returns zero bytes is interpreted to mean end of stream. However, the next read to that stream could return more bytes. This situation would arise if, for example,
\begin{itemize}
  \item the user hits \texttt{cntl-D} on an interactive tty stream, and then types more characters;
  \item input reaches the end of a disk file, but then some other process appends more bytes to the file.
\end{itemize}

Consequently, the following is \textit{not} guaranteed to be true:

\begin{verbatim}
let val z = end_of_stream f
val (a,f') = input f
val x = end_of_stream f'
in x=z (* not necessarily true! *)
\end{verbatim}

The "don't bother the reader" rule, combined with the definition of \texttt{end_of_stream}, guarantees that
\begin{equation*}
\texttt{end_of_stream}(f) = \texttt{end_of_stream}(f).
\end{equation*}

Implementors should beware that an empty buffer sometimes means end of stream, and sometimes not; I found an extra boolean variable necessary to keep track.
7 StreamIO

The functor StreamIO layers a buffering system on a primitive IO module:

```ml
functor StreamIO(structure PrimIO : PRIM_IO
    structure Vec: MONO_VECTOR
    structure Arr: MONO_ARRAY
    val some_elem : PrimIO.elem
    sharing type PrimIO.elem = Arr.elem = Vec.elem
    sharing type PrimIO.vector=Arr.vector=Vec.vector
    sharing type PrimIO.array=Arr.array
    sharing type PrimIO.pos=FilePosInt.int
) : STREAM_IO = ...
```

The Vec and Arr structures provide Vector and Array operations for manipulating the vectors and arrays used in PrimIO and StreamIO. The element some_elem is used to initialize buffer arrays; any element will do.

If flush_out finds that it can do only a partial write (i.e., writea_block or a similar function returns a "number of elements written" less than its "elems" argument) then flush_out must adjust its buffer for the items written and then try again. If the first or any successive write attempt returns zero elements written (or raises an exception) then flush_out raises an Io exception.

What is the behavior of the StreamIO primitives if a user interrupt occurs? Reppy thinks that losing information is preferable to printing output twice. This should be cogitated and clarified.

Implementation notes:

The previous section gives the specification of StreamIO behavior.

With buffered reading, a getpos operation on the instream may be done in the middle of a buffer. If find_pos is none in the underlying reader, then the StreamIO.getpos can be implemented by asking the current position (of the end of the buffer) and then subtracting. But find_pos is some(f), then the subtraction may not work, because elements may not correspond 1–1 to positions. In that case, it will be necessary to call find_pos; this in turn requires the position at the beginning of the buffer. But this means that the StreamIO system must do a getpos just before reading each new buffer, and remember the buffer position.8 (This is not necessary if find_pos=None.)

Here are some suggestions for efficient performance:

- Operations on the underlying readers and writers (read_block, etc.) are expected to be expensive (involving a system call, with context switch).

- Small input operations can be done from a buffer; the read_block or read_noblock operation of the underlying reader can replenish the buffer when necessary.

- Each reader may provide only a subset of read_block, read_noblock, block, can_input, etc. An augmented reader that provides more operations that can be constructed using PrimIO.augment_in; but it may be more efficient to use the functions directly provided by the reader, instead of relying on the constructed ones. The same applies to augmented writers.

---

8This is rather unfortunate.
• Keep the position of the beginning of the buffer on a multiple-of-chunksize boundary, and do read or write operations with a multiple-of-chunksize number of elements.

• For very large input_all or input_n operations, it is (somewhat) inefficient to read one chunksize at a time and then concatenate all the results together. Instead, it is good to try to do the read all in one large system call; that is, read_block(n). However, in a typical implementation of read_block this requires pre-allocating a vector of size n. If the user does input_all() or input_n(maxint), either the size of the vector is not known a priori or the allocation of a much-too-large buffer is wasteful. Therefore, for large input operations, query the size of the reader using endpos, subtract the current position, and try to read that much. But one should also keep things rounded to the nearest chunksize.

• The use of endpos to try to do (large) read operations of just the right size will be inaccurate if find_pos=some. But this inaccuracy can be tolerated: if the translation is anything close to 1−1, endpos will still provide a very good hint about the order-of-magnitude size of the file.

• Similar suggestions apply to very large output operations. Small outputs go through a buffer; the buffer is written with writea_block. Very large outputs can be written directly from the argument string using write_block.

• But how should the current buffer position be remembered? Either a getpos every time endpos is called, or a getpos when mk_instream is first called, followed by careful maintenance of the position of the beginning of the buffer. (Remember, mk_instream might be called only after the underlying reader has been moved away from the beginning position.)

• A lazy functional instream can (should) be implemented as a sequence of immutable (vector) buffers, each with a mutable ref to the next “thing,” which is either another buffer, the underlying reader, or an indication that the stream has been truncated.

• The input function should return the largest sequence that is most convenient; usually this means “the remaining contents of the current buffer.”

• To support non-blocking input, use reada_noblock if it exists, otherwise do can_input followed (if appropriate) by read_block.

• To support blocking input, use read_block if it exists, otherwise do reada_noblock followed (if would block) by block and then another reada_noblock.

• To support lazy functional streams, reada_block and reada_noblock are not useful; they are included only for completeness.

• Setpos_in, if setpos-ing forward, might choose to follow the buffer sequence, and can perhaps satisfy the setpos request without any underlying reader operation.

• Getpos_in, in some implementations, can tell the position without a system call, if it knows the position of the beginning of the buffer and the current position within the buffer.

• writea_block should, if necessary, be synthesized from write_block, and vice versa. Similarly for writea_noblock and write_noblock; reada_noblock and read_noblock; reada_block and read_block.
8 IO functor

The precise definition of "conventional" streams (IO signature) is in terms of "lazy functional" streams (STREAM_IO). The functor IO is provided:

```ml
functor IO(structure S : STREAM_IO) : IO = ...
```

The structures BinIO and TextIO are (presumably) built using separate applications of this functor (though TextIO is then enhanced with std_in, etc.), but users may apply the StreamIO and IO functors to make streams data types other than char and byte.

The semantics of IO are simple enough that it is sufficient to give a reference implementation.

```ml
functor IO(structure S : STREAM_IO) : IO =
  let abstraction I =
    struct
      structure StreamIO = S
      type instream = S.instream ref
      type outstream = S.outstream ref
      type elem = S.elem
      type vector = S.vector
      type pos = S.pos
      val mk_instream = ref
      val get_instream = !
      val set_instream = op :=
      val mk_outstream = ref
      val get_outstream = !
      val set_outstream = op :=
      val open_in = ref o S.open_in
      fun end_of f = if S.end_of_stream f then f else end_of(#2(S.input f))
    fun close_in(r as ref f) = (S.close_in f; r := end_of f)
    fun setpos_in(r as ref f, i) = r := S.setpos_in(f,i)
    val getpos_in = S.getpos_in o !
    val endpos_in = S.endpos_in o !
    fun input(r as ref f) = let val (v,f') = S.input f in r := f'; v end
    fun input_all(r as ref f) = let val v = S.input_all f
      in r := end_of f; v end
    fun input_noblock(r as ref f) =
      let val (v,f') = S.input_noblock f in r := f'; v end
    fun input1(r as ref f) = let val (v,f') = S.input1 f in r := f'; v end
    val end_of_stream = S.end_of_stream o !
    fun lookahead(ref f) = #1(S.input1 f)
  in I
end
```
Note that the **instream** and **outstream** types are abstract.

Some consequences of this definition:

The **end_of_stream** semantics are

\[
\text{fun end_of_stream (f as ref ff) = StreamIO.end_of_stream ff}
\]

This implies

\[
\text{let val x = end_of_stream f}
\text{val y = end_of_stream f}
\text{in x=y (* guaranteed true *)}
\]

Furthermore, second call to **end_of_stream** is guaranteed not to do any system call; this is a consequence of the "Don't bother the reader" semantics of **StreamIO.input**.

However, reading past end of stream is possible via **input**; the semantics may be straightforwardly derived from the semantics of **StreamIO.input**.

The output operations (which were not lazy functional to begin with) are even more similar between **STREAM IO** and **IO**. The only purpose of the extra **ref** in **IO** is to allow "output redirection."

### 9 Application Notes

#### 9.1 Random access reading/writing to the same stream

Instreams are instreams, outstreams are outstreams, and ne'er the twain shall meet. At least, not face to face. However, competent users can construct many things from the layered functors.

Here's an example: reading and writing to the same random-access file without re-opening it.\(^9\)

1. Open the file for reading, and for writing; extract the underlying reader and writer, discarding the buffering layer.

   \[
   \text{val reader = TextIO.StreamIO.get_reader (TextIO.StreamIO.open_in name)}
   \text{val writer = TextIO.StreamIO.get_writer (TextIO.StreamIO.open_out name)}
   \]

2. Do some buffered writes; then discard the buffering layer.

   \[
   \text{let val out = TextIO.mk_outstream(TextIO.StreamIO.mk_outstream(writer))}
   \text{in TextIO.setpos_out(out,some_pos);}
   \text{output(out,"Hello ");}
   \text{output(out,"World\n");}
   \text{flush_out out}
   \text{end}
   \]

3. Do some buffered reads; then discard the buffering layer.

\(^9\)The example here uses two file descriptors on the same file. This works fine on Unix; I'm not sure about other operating systems. Perhaps we should have a **PrimIO.open_in_out** function that produces a reader and a writer sharing a file descriptor (as a supplement to **PrimIO.open_in** and **PrimIO.open_out**). Or perhaps this function should be in some nonstandard module; it doesn't have to live inside the **PrimIO** module.
let val inf = TextIO.mk_instream(TextIO.StreamIO.mk_instream(reader))
  in TextIO.setpos_in(inf,another_pos);
  input inf;
  input inf
end

4. And so on. It’s cheap and easy to do \texttt{mk_instream} whenever switching between reading and writing.

\subsection{Other reader/writer devices}

The functions \texttt{open_in} and \texttt{open_out} provide system-default ways to create readers from “file names.”

SML implementations are likely to provide other ways to create readers and writers. For example,

\begin{verbatim}
structure Socket :
  sig  type socket_name
       structure P = TextIO.StreamIO.PrimIO
       val open_socket_text_reader: socket_name -> P.reader
       val open_bidirectional_socket: socket_name ->
           P.reader * P.writer
       ...
  end

Then the user could buffer these readers by using \texttt{mk_instream}.

Alternatively, a \texttt{Socket} interface could provide the high-level \texttt{instream}:

\begin{verbatim}
structure Socket :
  sig  type socket_name
       val open_socket_text_in: socket_name -> TextIO.instream
       val open_bidirectional_socket: socket_name ->
           TextIO.instream * TextIO.outstream
       ...
  end

and the user could extract the reader by using \texttt{get_instream} and \texttt{get_reader}.

Some operating systems have a notion of open for append; this differs from \texttt{open_out} followed by \texttt{setpos(endpos(f))} in that if \texttt{other} processes are also appending to the file, each successive write has an implicit \texttt{setpos} to end of file. An operating-system support module could provide a way to create an appending writer.$^{10}$

\subsection{String readers/writers}

A useful kind of reader/writer is an internal text queue, not using any devices at all:

\begin{verbatim}
local
  fun prim_pipe() : TextIO.StreamIO.PrimIO.reader *
      TextIO.StreamIO.PrimIO.writer =
\end{verbatim}

\footnote{Or should this be a standard feature of \texttt{TextIO}?}
fun pipe() : instream * outstream =
  (* layer mk_instream and mk_outstream on
  components of prim_pipe() *)
end

It would be natural to provide such functions in a library.

Here's an even simpler example:

fun string_reader(source : string) : TextIO.StreamIO.PrimIO.reader =
  let val pos = ref 0
  fun read n = let val p = !pos
    val m = min(n, size source - p)
    in pos := p+m; substring(source,p,m)
  end
Rd{read_noblock = SOME(fn n => SOME(read n)),
  reada_noblock = NONE,
  read_block = SOME(read),
  reada_block= NONE,
  block = SOME(fn()=>()),
  can_input = SOME(fn()=>true),
  name="<string>",
  chunksize=size source,
  close=fn()=>(),
  getpos=SOME(fn()=>!pos),
  setpos=SOME(fn k => if 0<=k andalso k <= size source then pos:=k
    else raise Io{ml_op="setpos",name="<string>",os_op="",
    reason="position out of bounds",
    syserror=OS.noError}),
  endpos=SOME(fn()=>size source)}
end

val open_string : string -> instream =
  TextIO.mk_instream o TextIO.StreamIO.mk_instream o string_reader

9.4 Translated readers

Sometimes one wants to apply a translation function to a stream. For example, one might
want to translate CR-LF to LF on input, or translated escape-coded ASCII into Unicode. I
shall discuss translated input streams (readers) here, but the same ideas apply to translated
output streams (writers).

Since anyone is allowed to counterfeit a reader, it is easy to write a translation function
on readers:

fun translate1 (source: TextIO.PrimIO.reader) : TextIO.PrimIO.reader
or
fun translate2 (source: BinIO.PrimIO.reader) : TextIO.PrimIO.reader

Here's an example:
fun remove_CR(rd0 as TextIO.StreamIO.PrimIO.Rd rd) :
  let fun charCR(\"\013\") = "" 
      | charCR c = implode c 
  fun stringCR s = concat(mapChar charCR (s,0,size s)) 
  fun option f NONE = NONE 
      | option f (SOME x) = SOME(f x) 
  fun retranslate(_,0,pos) = pos 
      | retranslate(read,nelems,pos) = 
        let val s = read nelems 
          val len = size s 
          fun loop(i,n,p) = if i=s then retranslate(read,n,p) 
            else if n=0 then p 
            else if CharVector.sub(s,i) = \"\013\" 
              then loop(i+1,n,p) 
              else loop(i+1,n-1,p) 
        in loop(0,nelems,pos) 
      end 
  in TextIO.StreamIO.PrimIO.Rd{
    read_noblock = option (fn get => option stringCR o get) (#read_noblock rd,)
    reada_noblock = (* etc. *),
    read_block = option (fn get => stringCR o get) (#read_block rd),
    reada_block= (* etc. *),
    block = #block rd,
    can_input = #can_input rd,
    name= #name rd,
    chunksize= #chunksize rd,
    close= #close rd,
    getpos=#getpos rd,
    setpos=#setpos rd,
    endpos=#endpos rd,
    find_pos= (case (#getpos rd, #setpos rd, 
                     TextIO.StreamIO.PrimIO.augment_in rd0)
              of (SOME get, SOME set, 
                     TextIO.StreamIO.PrimIO.Rd{read_block=readb,...}) =>
                SOME(fn ({data,first,nelems},pos) => 
                  let val p0 = get() 
                    val p1 = (set(pos); 
                      retranslate(readb,nelems,pos)) 
                    in set(p0); p1 
                  end) 
                | _ => NONE) 
      end)
be provided, or getpos, setpos, and endpos must not be provided. Here we have chosen
to provide find_pos whenever possible. Because the translation is not invertible (we don’t
know where the CR characters might have been), find_pos must re-read the original stream.

Users who need to do random access on translated streams might also use a solution
similar to the one in section 9.1: do setpos on the underlying, untranslated reader. Then,
after each setpos, apply afresh the translation function (such as remove_CR and then
apply a new buffer (via mk_instream).

9.5 Abstract positions

In applications where one wants seekable, translated readers with “moded escapes” it is difficult
represent positions as integers. This will happen if escape characters semi-permanently
change the translation state of a stream, rather than affecting just the next character.

In such a case, one might want to have an abstract data type position, perhaps with a
total ordering but without a mapping to integers.

One way to accomplish this is to make a new structure matching the PRIM_IO signature:

```
abstraction MyPrimIO : PRIM_IO =
  sig type pos = string (* or whatever *)
  datatype reader = Rd of ....
  ...
end
```

Now one can write translated readers that can deal with translated positions more flexibly,
since there’s no 1–1 correspondence property that must be maintained.

The only problem is that the standard StreamIO functor cannot be applied, because
the sharing constraint type pos=nt is violated.¹¹

The user can write his own buffering functor:

```
functor MyStreamIO(structure PrimIO : PRIM_IO ...
  (* not sharing type PrimIO.pos=nt *)
  ) : STREAM_IO = struct ... end
```

structure MyIO = MyStreamIO(structure PrimIO = MyPrimIO ...)

Now MyIO.instream is a different type than TextIO.StreamIO.instream. If one didn’t rely
on pos=int, then one could still make use of the MyIO interface:

```
functor MyApplication(IO : STREAM_IO) = struct ... end
```

Also, it is possible to write a function to translate a MyPrimIO.reader into an ordinary
PrimIO.reader (but with setpos disabled):

```
fun standardize (MyPrimIO.Rd rd) =
  TextIO.StreamIO.PrimIO.Rd{
    read_noblock = #read_noblock rd,
```

¹¹The sharing of pos=FilePosInt.int is useful to clients of StreamIO. Perhaps it is not necessary for
the internals of the functor. If that were the case, then it would not be necessary to define the functor
MyStreamIO, because functor StreamIO could be used. But MyIO would still be incompatible with
TextIO.StreamIO.
9.6 Lexical analysis

Lexical analyzers need to process their input efficiently, and often need some amount of lookahead. Line-oriented applications need to read one line of text at a time, efficiently. Both of these applications can make effective use of lazy-stream input.

Consider the implementation of an input_line function, that reads up to the next newline character. A naive implementation would read characters, then concatenate them:

```ml
fun input_line (f: TextIO.instream) =
  let fun loop () = case input1 f
    of SOME("\n") => "\n"
     | SOME c => c :: loop()
     | NONE => nil
  in implode (loop())
end
```

Now, we may wish to avoid all the list construction and `implode` call.\(^{12}\) Thus:

```ml
fun input_line (f: TextIO.instream) =
  let val g0 = TextIO.get_instream f
    fun loop(i,g) = case input1 g
      of (SOME("\n"),_) => i+1
       | (SOME c, g') => loop(i+1,g')
       | (NONE,_) => i
    in TextIO.input_n(loop(0,g0))
  end
```

This has the effect of looking through the input buffer for a newline character, then extracting just the right-length string from the input buffer; but it's all done abstractly.

There are no list constructions, and only one string copy: the extract implied by the `input_n` call.\(^{13}\) On the other hand, there is a function call for each character; I do not see this as a problem. We expect ML programs (or, in fact programs in any language)

\(^{12}\)Is this still called `implode` in the new basis?
\(^{13}\)There is some building of `SOME` constructors. We must still discuss whether `input1` should return a char option, or just return a char with exception on end of file. But that's a separate issue. However, in the `input_line` function I show here, raising the exception leads to natural, efficient behavior if we also change the semantics of `input_line` to say that an exception should be raised if the last line of the file does not end with a newline character.
to implement abstract data types via a function-call interface; if this becomes a source of inefficiency, perhaps the solution is for compilers to implement cheaper function calls.

A very similar approach works for lexical analyzers which do more general (perhaps multi-character) lookahead: First scan the lazy stream to determine the length of the token, then use `input_n` to extract it and advance the stream.

10 Loose ends

What about opening files for append?

What about user (and other) interrupts during buffered I/O operations?
