Proposed interface for Standard ML Stream I/O

Andrew W. Appel
January 31, 1995

1 Introduction

The Input/Output interface provides:

- buffered reading and writing;
- arbitrary lookahead, using an underlying “lazy streams” mechanism;
- dynamic redirection of input or output;
- random access;
- uniform interface to text and binary data;
- layering of stream translations, through an underlying “reader/writer” interface;
- unbuffered input/output, through the reader/writer interface or even through the buffered stream interface;
- primitives sufficient to construct facilities for random access reading/writing to the same file.

In addition, the prescriptions and recommendations herein allow for efficient implementation, minimizing system calls and memory-memory copying.

The I/O system has several layers of interface. From bottom to top, they are

**PRIM.IO** Uniform interface for unbuffered reading and writing at the “system call” level, though not necessarily via actual system calls.

**STREAM.IO** Buffered “lazy functional stream” input; buffered conventional output.

**IO** Buffered, conventional (side-effecting) input and output with redirection facility.
Because most programmers will use the IO interface, I will describe that first, rather informally. Then I will go bottom-up over the entire system, giving a technical specification of the interfaces, and their axioms and pragmatics.¹

## 2 IO

Conventional buffered input/output is done using several structures matching the IO signature: **TextIO**, for character input/output, **BinIO**, for binary (byte) input/output.

```haskell
signature IO =
  sig
    type instream
    type outstream
    type elem
    type vector
    type pos
    val closeIn : instream -> unit
    val input : instream -> vector
    val inputAll : instream -> vector
    val inputNoblock : instream -> vector option
    val input1 : instream -> elem option
    val inputN : instream * int -> vector
    val endOfStream : instream -> bool
    val lookahead : instream -> elem option
    val setPosIn : instream * pos -> unit
    val getPosIn : instream -> pos
    val endPosIn : instream -> pos
    val closeOut : outstream -> unit
    val output : (outstream * vector) -> unit
    val output1 : outstream * elem -> unit
    val flushOut : outstream -> unit
    val getPosOut : outstream -> pos
    val endPosOut : outstream -> pos
    val setPosOut : outstream * pos -> unit
  structure StreamIO : STREAM_IO
    sharing type elem = StreamIO.elem
    sharing type vector = StreamIO.vector
    sharing type pos = StreamIO.pos
    val mkInstream : StreamIO.instream -> instream
    val getInstream : instream -> StreamIO.instream
```

¹All footnotes in this document indicate unresolved issues. Issues should be resolved, and footnotes removed, by the last draft.
val setInstream : instream * StreamIO.instream -> unit
val mkOutstream : StreamIO.outstream -> outstream
val getOutstream : outstream -> StreamIO.outstream
val setOutstream : outstream * StreamIO.outstream -> unit
end

structure FilePosInt : INTEGER

signature STANDARD_IO =
sig
  include IO
  val openIn : string -> instream
  val openOut : string -> outstream
  val openAppend : string -> outstream
  val stdIn : instream
  val stdOut : outstream
  val stdErr : outstream
end
signature BIN_IO =
sig
  include STANDARD_IO
  sharing type pos = FilePosInt.int
  sharing type StreamIO.elem = Word8.word
  sharing type StreamIO.vector = Word8Vector.vector
end
signature TEXT_IO =
sig
  include STANDARD_IO
  sharing type StreamIO.elem = char
  sharing type StreamIO.vector = string
  sharing type pos = FilePosInt.int
  val inputLine : instream -> string
  val translateIn : BinIO.StreamIO.PrimIO.reader ->
    TextIO.StreamIO.PrimIO.reader
  val translateOut : BinIO.StreamIO.PrimIO.writer ->
    TextIO.StreamIO.PrimIO.writer
end

structure BinIO : BIN_IO
structure TextIO : TEXT_IO

These operations may raise the General.io exception:

exception Io of name : string,
  function : string,
  cause : exn
Operations on instreams

**elem**
A single element (member of a stream); for TextIO streams this is `char`; for BinIO this is `Word8.word`.

**vector**
A sequence of elements (such as `string` or `Word8Vector.vector`).

\[ f = \text{openIn}(s) \]
Opens a file named `s` as a stream `f`.\(^4\)

\[ \text{closeIn}(f) \]
Close `f`; no further operations are permitted on `f` (they will raise the Io exception).

\[ v = \text{input}(f) \]
Read some elements of `f`, returning a vector `v`. If (and only if) `f` is at end of file, `size(v) = 0`. May block (not return until data is available in the external world).

\[ v = \text{inputAll}(f) \]
Return the vector `v` of all the elements of `f` up to end of stream.

\[ \text{inputNoBlock}(f) \]
If any elements of `f` can be read without blocking, return at least one of them. If it is possible to determine without blocking that `f` is at end of stream, return `SOME(empty)`.
Otherwise return `NONE`.

\[ c = \text{input1}(f) \]
If at least one element `e` of `f` is available, return `SOME(e)`. If `f` is at end of file, return `NONE`. Otherwise block until one of those conditions occurs.

\[ v = \text{inputN}(f, n) \]
If at least `n` elements remain before end of stream, return the first `n` elements. Otherwise, return the (possibly empty) sequence of elements remaining before end of stream. Blocks if necessary. (This was the behavior of the `input` function in the 1989 *Definition of Standard ML*, and pre-1.00 releases of SML/NJ.)

\[ \text{endOfStream}(f) \]
False if any elements are available in `f`; true if `f` is at end of stream. Otherwise blocks until one of these conditions occurs. Exactly equivalent to `(size(input f)=0)`.

\(^4\)Unfortunately, there's no way to get hold of the standard input and standard output as binary streams.
\(c = \text{lookahead}(f)\)

Return the next element without advancing the stream; or at end of file
return \text{NONE}. Multiple-character lookahead can be accomplished with the
lazy functional stream interface; see section 6.

\text{setPosIn}(f,i)

Seek to position \(i\) in \(f\). \textit{Not always supported (raises Io if not supported on } f)\).

\(i = \text{getPosIn}(f)\)

Tell the current position of \(f\). For the standard modules \text{TextIO} and
\text{BinIO}, \(i\) is an integer equal to the number of elements since the beginning
of the file. Positions correspond 1–1 to elements in the file, and are not in
any way abstract. \textit{Not always supported (raises Io if not supported on } f)\).

\(i = \text{endPosIn}(f)\)

Tell the ending position of \(f\). For the standard modules \text{TextIO} and
\text{BinIO}, \(i\) is an integer equal to the number of elements in the file. \textit{Not
always supported (raises Io if not supported on } f)\).

\textbf{Operations on outstreams}

\text{closeOut}(f)

Flush \(f\)'s buffer and close the stream (releasing operating-system resources
associated with it).

\text{output}(f,v)

Write the sequence \(v\) to \(f\).

\text{output1}(f,x)

Write the element \(x\) to \(f\).

\text{flushOut}(f)

Flush \(f\)'s buffer: that is, make the underlying file reflect any previous
\text{output} operations.

\(i = \text{getPosOut}(f)\)

Tell the current position of \(f\) (\textit{not always supported, may raise exception}).

\(i = \text{endPosOut}(f)\)

Tell the ending position of \(f\) (\textit{not always supported, may raise exception}).
\textit{Not always supported (raises Io if not supported on } f)\).

\text{setPosOut}(f,i)

Seek to position \(i\) of \(f\) (\textit{not always supported, may raise exception}). Positions
may not correspond 1–1 to elements in the file, but should increase
monotonically.
Any of these functions may raise the Io exception if an operation fails (including closeOut if a buffer cannot be flushed).

Random access
In order to avoid unnecessary limitations on file sizes, the getPos, endPos, setPos functions all operate on special FilePosInt integers:

structure FilePosInt: INTEGER

FilePosInt.int is abstract and does not share with Int.int or with any other integer type.

Users can operate on the pos type using FilePosInt. + and FilePosInt. - ; or (at the risk of being unable to process large files) convert to/from ordinary integers using FilePosInt.toDefault and FilePosInt.fromDefault

STANDARD_IO
The IO signature describes operating-system-independent input and output streams. Implementations may provide many ways of creating instreams and outstreams, using network connections, special devices, ML functions that generate or consume elements on the fly, and so on.

But in many contexts a standard way of opening files (named by simple strings)—and standard input, output, and error streams—will suffice. The STANDARD_IO signature includes IO, plus:

\[ f = \text{openIn}(s) \]
Open the file named \( s \) for reading.

\[ f = \text{openOut}(s) \]
Open the file named \( s \) for writing at the beginning, truncating it if it already exists, creating it if not.

\[ f = \text{openAppend}(s) \]
Open the file named \( s \) for writing at the end, creating it if it does not already exist. On Unix and other operating systems that support "atomic append mode," each individual flushOut operation (or other output operation that flushes the buffer) appends atomically to the current end of file, even if other processes are appending to the same file between flushOut operations. The openAppend function opens a file in this mode, if possible. Streams opened for atomic append will not support random access (getPos, setPos).

stdIn
The standard input stream.
stdOut
The standard output stream.

stdErr
The standard stream for writing error messages.

Both TextIO and BinIO have stdIn streams (of different types), but these are implemented on the same underlying file. Users who do buffered input on both TextIO.stdIn and BinIO.stdIn will see arbitrary interleaving. The treatment of stdOut and stdErr is analogous.

TEXT_IO
Text streams (TextIO.instream) contain lines of text and control characters. Text lines are terminated with "\n" characters.

On operating systems that use CR-LF or CR as line terminators, these will be translated to single "\n" characters. The inverse translation will be one on output.

More substantial translation will be done on operating systems that use, for example, escape-coded Unicode text files.

The TextIO structure provides, in addition to STANDARD_IO, s = inputLine(f)
Read one line from a text file, returning characters up to and including the next newline character. If end-of-file is reached before a newline character, all characters remaining in the file are returned. Thus, if end-of-file is reached immediately, the empty string will result.

f = translateIn(g)
The default (operating-system specific) translation from binary instreams to text instreams.

f = translateOut(g)
The default (operating-system specific) translation from binary outstreams to text outstreams.

Closing files on program exit
All streams created by TextIO.openIn, TextIO.openOut, BinIO.openIn, and BinIO.openOut will be closed (the outstreams among them flushed) when the ML program exits. The outstreams stdOut and stdErr will be flushed, but not closed, on program exit.
Redirecting IO streams

There is also a set of primitives to relate IO streams to the “lazy functional streams” model of input/output; and thus to the underlying unbuffered reader/writer primitives:

**StreamIO**

The particular instantiation of the `STREAM_IO` interface underlying this IO module (i.e., streams of bytes, chars, or some other element type).

\[ f = \text{mkInstream}(s) \]

Create a conventional stream \( f \) from a functional stream \( s \).

\[ s = \text{getInstream}(f) \]

Extract the functional stream \( s \) from \( f \). This allows arbitrary lookahead; for example:

```plaintext
fun lookaheadN(f, n) = 
  let val f' = mkInstream(getInstream(f)) 
  in inputN(f', n) 
  end
```

This makes a “copy” \( f' \) of the stream \( f \); then input operations in \( f' \) won’t affect \( f \) (though `setPosIn` on \( f' \) may effectively close \( f \)). For more details, see sections 4, 5, 6, 7, and 8, which give a more precise specification of stream behavior.

\[ \text{setInstream}(f, s) \]

Redirect \( f \), so that further input comes from \( s \). For example:

```plaintext
fun fromFile(g, name) = 
  let val f = openIn name 
    val saveStdIn = getInstream stderr 
  in setInstream(stdIn, getInstream f); g(); setInstream(stdIn, saveStdIn) 
  end
```

For more details, see the next few sections.

\[ f = \text{mkOutstream}(s) \]

Create a conventional outstream \( f \) from a `StreamIO.outstream` \( s \). The output streams in `StreamIO` are not “functional,” they are conventional streams operated on by side-effecting output. The difference between an `IO.outstream` and a `StreamIO.outstream` is that the former may be redirected using `setOutstream`. Think of the former as a ref of the latter.
\[ s = \text{getOutstream}(f) \]

Extract the underlying outstream \( s \) from the redirectable outstream \( f \).

Unfortunately, \( s \) is not "pure functional," so there's no equivalent of the lookahead trick shown above. Unlike instreams, if

\[
\text{val } f' = \text{mkOutstream(getOutstream } f) 
\]

then operations on \( f' \) are equivalent to operations on \( f \).

\text{setOutstream}(f, s)

Useful for redirecting output. For example,

\[
\text{fun toFile}(g, name) = \\
\text{let } \text{val } f = \text{TextIO.openOut name} \\
\text{val saveStdOut = getOutstream stdOut} \\
\text{in setOutstream}(\text{stdOut, getOutstream } f); \\
\text{g}(); \\
\text{setOutstream}(\text{stdOut, saveStdOut}) \\
\text{end} 
\]

In can be argued that this is not very elegant; the function \( g \), instead of writing stuff to \( \text{stdOut} \), should have been parameterized (in the usual ML way) on an \textbf{outstream} from the very beginning. Then the \textit{get} and \textit{set} primitives wouldn't be needed.

\section*{Translation}

In some environments, the external representation of a text file is different from its internal representation: for example, in MS-DOS, text files on disk contain CR-LF, and in memory contain only LF at the end of each line. Binary streams (\textit{BinIO.instream}) match the external files byte for byte; text streams (\textit{TextIO.instream}) are translated. Normally, users of \textit{TextIO} will not need to know or care about this translation; but for more sophisticated users, the translation functions are made visible as \textit{TextIO.translateIn} and \textit{TextIO.translateOut}. On Unix systems, these will be identity functions. See section 9.4.

\section{OS}

The primitive I/O (\textit{PrimIO}), stream I/O (\textit{StreamIO}), and standard I/O (\textit{IO}) packages require only these components of the OS structure:

\text{structure OS : sig}
\begin{align*}
\text{type syserror} \\
\text{exception SysErr } \\
\end{align*}

9
For basic "operating system" functions such as reading and writing, the input/output modules do not reference the OS structure directly. Instead, each stream is built on a PrimIO.reader or PrimIO.writer; the readers and writers contain functions that can accomplish the system calls. But it is also possible for users to synthesize readers or writers that don't do system calls at all, or do unconventional ones. The parameterization of IO on "readers" and "writers" is described in the next section.

4 PRIM_IO

Primitive I/O is meant to be an abstraction of the system call operations commonly available on file descriptors.

signature PRIM_IO =
  sig
    type elem
    type vector
    type array
    type pos
    datatype reader = Rd of
      readBlock : (int -> vector) option,
      readaBlock: (data: array, first: int, nelems: int -> int) option,
      readNoBlock : (int -> vector option) option,
      readaNoBlock: (data: array, first: int, nelems: int -> int option) option,
      block : (unit -> unit) option,
      canInput : (unit -> bool) option,
      name : string,
      chunkSize : int,
      close : unit -> unit,
      getPos : unit -> pos,
      newPos : data: vector, first: int, nelems: int*pos -> pos,
      setPos : (pos -> unit),
      endPos : (unit -> pos)
    datatype writer = Wr of
    
    datatype Pos = Pos of
      pos : int
    end

writeNoBlock: (data: vector, first: int, nelems: int -> int option) option,
writeaNoBlock: (data: array, first: int, nelems: int -> int option) option,
writeBlock: (data: vector, first: int, nelems: int -> int) option,
writeaBlock: (data: array, first: int, nelems: int -> int) option,
block: (unit->unit) option,
canOutput: (unit->bool) option,
name: string,
chunkSize: int,
close: unit -> unit,
getPos : (unit->pos),
setPos : (pos->unit),
endPos : (unit->pos)
val augmentIn : reader -> reader
val augmentOut: writer -> writer
end

A file (device, etc.) is a sequence of "elements" (elem), which may (for example) be characters or bytes. The distinction between characters and bytes is necessary on DOS, where CR-LF is translated to LF when reading character files; or on Windows-NT where characters are 16-bits (Unicode) and bytes are 8 bits.

One typically reads or writes a sequence of elements in one system call: this sequence is the vector type. Sometimes it is useful to write the sequence from a mutable array instead of from the vector.

A reader is a file (device, etc.) opened for reading, and a writer one opened for writing.

The components of a reader are

close()

Closes the reader (for example, frees operating system resources). Further operations to this reader are illegal and must be checked for by the reader (the Io exception must be raised).

name

The name associated with this file or device, for use in error messages shown to the user.

chunkSize

The recommended (efficient) size of read operations on this reader. This is typically to the block size of the operating system's buffers. If that is not known, a value of 2048 or 4096 will probably work well. ChunkSize =
1 strongly recommends (but cannot guarantee, since buffering occurs in other modules, not this one) unbuffered I/O on this reader. **ChunkSize** = 0 is illegal.

**readNoBlock(n)**
(optional) Reads i elements without blocking, for 0 < i ≤ n creating a vector v, returning some(v); or (if a read would block) returns none.

**readBlock(n)**
(optional) Reads i elements for 0 < i ≤ n returning a vector v of length i; blocks (waits) if necessary until at least one element is available.

**readaNoBlock**{buf=a,first=i,nelems=n}
(optional) Reads k elements without blocking, for 0 < k ≤ n into a1,...,a1+k−1, returning some(k); if no elements remain before end-of-file, returns some(0) without blocking; or (if a read would block) returns none.

**readaBlock**{buf=a,first=i,nelems=n}
(optional) Reads k elements for 0 < k ≤ n into a1,...,a1+k−1, returning a vector k; blocks (waits) if necessary until at least one element is available. If no elements remain before end-of-file, returns 0.

**block()**
(optional) Returns only when at least one element is available for read without blocking.

**canInput()**
(optional) Returns true iff the next read can proceed without blocking.

**p = getPos()**
Tells the current position in the file. Useful even for non-seekable files, especially if the **endPos** function is provided (because large input operations are more efficient if the distance from "here to end of file" is known). The **getPos** function must be nondecreasing (in the absence of **setPos** operations, or other interference to the underlying object). Where **setPos** is not provided, the reader can just count the elements returned from read operations and **getPos** can tell the count. But an implementation of **getPos** that always returns zero is legal.

**p' = findPos**{data = v,first = i,nelems = n},p
Tells the position p' of the (i+n)th element of the vector v, assuming that the position of the ith element is p. Section 9.4 explains why this is useful.

**setPos(i)**
(optional) Move to position i in file. Optional, in the sense that it may raise an exception if unimplemented or invalid.
endPos()

The position at the end of the file. Optional, in the sense that it may raise an exception if unimplemented, or invalid on this reader.

One of readBlock, readaBlock, readNoBlock, or readaNoBlock must be provided.

Providing more of the optional functions increases functionality and/or efficiency of clients:

1. Absence of all of readBlock, readaBlock, and block means that blocking input is not possible.

2. Absence of all of readNoBlock, readaNoBlock, and canInput means that non-blocking input is not possible.

3. Absence of readNoBlock means that non-blocking input requires two system calls (using canInput, readBlock).

4. Absence of readaNoBlock or readaBlock means that input into an array requires extra copying. But I do not anticipate that reading into arrays will normally be very important in the “lazy functional stream” model.

Clients of PrimIO are required to synthesize blocking reads from readNoBlock + block, synthesize vector reads from array reads, synthesize array reads from vector reads, as needed—so the PrimIO.reader is required to provide only a minimum set. If the reader can provide more than the minimum set in a way that is more efficient than the obvious synthesis than by all means it should do so. Providing more than the minimum by just doing the obvious synthesis inside the PrimIO layer is not recommended because then clients won’t get the “hint” about which are the efficient (“recommended”) operations.

The augmentIn function takes a reader r and produces a reader in which as many as possible of readBlock, readaBlock, readNoBlock, readaNoBlock are provided, by synthesizing these from the operations of r.

5. Absence of endPos means that very large inputs (where vectors must be pre-allocated) cannot be done efficiently (in one system call, without copying).

6. The client is likely to call getPos on every read operation. Thus, the reader should maintain its own count of (untranslated) elements to avoid repeated system calls. This should not be done on streams opened for atomic append, of course, where the information cannot be obtained except by a system call.
7. Absence of `setPos` prevents random access.

8. The `findPos` function is needed in conjunction with readers that do translation, so that positions do not always correspond 1-1 to elements returned from `read`. If the translation function is invertible, then `findPos` will be straightforward to implement. If not invertible, then `findPos` can seek to `pos` in the underlying file, and re-translate forward to the right point. In that case, the implementation of `findPos` will probably require: `p0 = get()`, `setPos(pos)`, `read`, `setPos(p0)` to restore the file position to what it was before the `find` operation.

9. Readers that do no translation, so that positions do correspond 1-1 to elements returned from the `read` functions, can provide a very simple `findPos` function:

   ```
   fun find([data,first,nelems],p) =
   FilePosInt.*(p, FilePosInt.fromDefault nelems)
   ```

10. Readers whose `getPos` always returns zero should also have a `findPos` that always returns zero.

The components of a `writer` are:

`writeNoBlock{buf=v,first=i,nelems=n}`
This (optional) function without blocking writes elements `vI,...,vI+k-1`, for `k <= n` to the output device, and returns `SOME(k)`; or (if the write would block) returns `NONE`. `k = 0` is not recommended (prohibited?).

`writeaNoBlock{buf=a,first=i,nelems=n}`
This (optional) function without blocking writes elements `aI,...,aI+k-1`, for `k <= n` to the output device, and returns `SOME(k)`; or (if the write would block) returns `NONE`. `k = 0` is not recommended (prohibited?).

`writeBlock{buf=v,first=i,nelems=n}`
This (optional) function writes elements `vI,...,vI+k-1`, for `0 < k <= n` to the output device, and returns `k`. If necessary, waits (blocks) until the external world can accept at least one element.

`writeaBlock{buf=a,first=i,nelems=n}`
This (optional) function writes elements `aI,...,aI+k-1`, for `0 < k <= n` to the output device, and returns `k`. If necessary, waits (blocks) until the external world can accept at least one element.

`writeNoBlock{buf=v,first=i,nelems=n}`
This (optional) function writes elements `vI,...,vI+k-1`, for `0 < k <= n` to the output device without blocking, and returns `SOME(k)`; or (if the write would block) returns `NONE`.
writeaNoBlock\{buf=a,first=i,nelems=n\}
  This (optional) function writes elements \(u_1, \ldots, u_{i+k-1}\), for \(0 < k \leq n\) to
  the output device without blocking, and returns \textit{some} \((k)\); or (if the write
  would block) returns \textit{none}.

\textbf{block()}
  This (optional) function does not return until the writer is guaranteed to
  be able to write without blocking.

\textbf{canOutput()}
  (optional) Returns \textit{true} iff the next write can proceed without blocking.

\textbf{name}
  The name associated with this file or device, for use in error messages
  shown to the user.

\textbf{chunkSize}
  The recommended (efficient) size of write operations on this writer. This
  is typically to the block size of the operating system’s buffers. If that is not
  known, a value of 2048 or 4096 will probably work well. \textit{ChunkSize} =
  1 strongly recommends (but cannot guarantee, since buffering occurs in
  other modules, not this one) unbuffered I/O on the writer. \textit{ChunkSize} \leq
  0 is illegal (functions in other modules taking writers as arguments may
  raise exceptions).

\textbf{close()}
  Closes the writer (for example, frees operating system resources devoted
  to this writer). Further operations to this writer are illegal and must be
  checked for by the writer.

\textbf{getPos()}
  (optional) Tells the current position within the file. Most useful on seek-
  able writers.

\textbf{endPos()}
  (optional) The position at the end of the file.

\textbf{setPos(i)}
  (optional) Moves to position \(i\) in the file, so future writes occur at this
  position.

One of \texttt{writeBlock}, \texttt{writeaBlock}, \texttt{writeNoBlock}, or \texttt{writeaNoBlock}
must be provided. Providing more of the optional functions increases function-
ality and/or efficiency of clients:

1. Absence of all of \texttt{writeBlock}, \texttt{writeaBlock}, and \texttt{block} means that block-
   ing output is not possible.
2. Absence of all of `writeNoBlock`, `writeaNoBlock`, and `canOutput` means that non-blocking output is not possible.

3. Absence of `writeNoBlock` means that non-blocking output requires two system calls (using `canOutput`, `writeBlock`).

4. Absence of `writeaBlock` or `writeaNoBlock` means that extra copying will be required to write from an array.

5. Absence of `writeaNoBlock`, `writeNoBlock`, and `canOutput` from a writer means that nonblocking output is impossible. But the standard `StreamIO` modules do not support nonblocking output anyway.

6. Absence of `setPos` prevents random access.

The `augmentOut` function takes a writer \( w \) and produces a writer in which as many as possible of `writeBlock`, `writeaBlock`, `writeNoBlock`, `writeaNoBlock` are provided, by synthesizing these from the operations of \( w \).

Exceptions The PrimIO functions (component fields of readers and writers) may raise the following exceptions:

- **Subscript** for any function taking the \( \{data, first, nelems\} \) type, if \( first \) and \( nelems \) imply an out-of-bounds reference to \( data \).
- **SysErr** for any function that performs a system call.
- **Fail** for any other error.

Note that the **Io** exception is not raised. This means that higher layers of abstraction (i.e., `StreamIO`) do not have to check for it.

## 5 PrimIO

The functor `PrimIO` builds standard instances of the `PRIM_IO` signature.

```ocaml
defunctor PrimIO(structure A : MONO_ARRAY
  structure V : MONO_VECTOR
  sharing type A.elem = V.elem
  val someElem : A.elem
  structure Pos : INTEGER) : PRIM_IO =
struct . . . end
```

The only nontrivial parts of the PrimIO functor are the implementations of the functions `augmentIn`, and `augmentOut`, etc. simulate one kind of reader (or writer) functionality in terms of other kinds. For example:
fun augmentIn (r as Rd r') =
  let fun readaToRead reada i =
    let val a = A.array(i,someElem)
      val i' = reada{data=a,first=0,nelems=i};;
    in A.extract(a,0,i')
  end

  val readBlock' =
  case r
  of Rd{readBlock=SOME f,...} => SOME f

end

6 STREAM\_IO

The Stream I/O interface provides buffered reading and writing to input and output streams.

Input streams are treated in the lazy functional style: that is, input from a stream \( f \) yields a finite vector of elements, plus a new stream \( f' \). Input from \( f \) again will yield the same elements; to advance within the stream in the usual way it is necessary to do further input from \( f' \). This interface allows arbitrary lookahead to be done very cleanly, which should be useful both for ad hoc lexical analysis and for table-driven, regular-expression-based lexing.

Output streams are handled more conventionally, since the lazy functional style doesn't seem to make sense for output.

signature STREAM\_IO =
  sig
    structure PrimIO: PRIM\_IO
      type elem sharing type elem = PrimIO.elem
      type vector sharing type vector = PrimIO.vector
      type pos sharing type pos = PrimIO.pos
      type instream
      type outstream
    val mkInstream : PrimIO.reader -> instream
    val closeIn : instream -> unit
  end

17
val setPosIn : instream * pos -> instream
val getPosIn : instream -> pos
val endPosIn : instream -> pos
val input : instream -> vector * instream
val inputAll : instream -> vector
val inputNoblock : instream -> (vector * instream) option
val inputI : instream -> elem option * instream
val inputN : instream * int -> vector * instream
val endOfStream : instream -> bool
val getReader : instream -> PrimIO.reader
val mkOutstream : PrimIO.writer -> outstream
val closeOut : outstream -> unit
val output : (outstream * vector) -> unit
val outputI : (outstream * elem) -> unit
val flushOut : outstream -> unit
val getPosOut : outstream -> pos
val setPosOut : outstream * pos -> unit
val endPosOut : outstream -> pos
val getWriter : outstream -> PrimIO.writer
end

Each instream \( f \) can be viewed as a sequence of "available" elements (the buffer or sequence of buffers) and a mechanism (the reader) for obtaining more. After an operation \((v,f') = \text{input}(f)\) it is guaranteed that \( v \) is a prefix of the available elements. In a "truncated" instream, there is no mechanism for obtaining more, so the "available" elements comprise the entire stream. In a "terminated" outstream, there is no mechanism for outputting more, so any output operations will raise the \text{Io} exception.

**PrimIO**

Every instance of \text{STREAM}\text{IO} is built over an instance of \text{PRIM}\text{IO}.

**elem**

A single element (member of a stream).

**vector**

A sequence of elements, just as in \text{PRIM}\text{IO}.

\( f = \text{mkInstream}(r) \)

Create a buffered stream \( f \) from a reader \( r \). (Most users will normally use \text{TextIO.openIn} instead.)

\( \text{closeIn}(f) \)

Truncate \( f \), and release operating system resources associated with the underlying file (if any).
$g = \text{setPosIn}(f, i)$
Now $g$ is a new instream starting from position $i$ of $f$. $f$ may or may not
be truncated, depending on whether the setPos request can be satisfied
within the buffer. (Nondeterministic behavior! is that bad?) \textit{Not always
supported.}

$\text{getPosIn}(f)$
Return the current position of $f$. \textit{Not always supported.}

$\text{endPosIn}(f)$
Return the position at end of file of $f$. \textit{Not always supported.}

$(u, f') = \text{input}(f)$
If any elements of $f$ are available, return sequence $v$ of one or more ele-
ments and the “remainder” $f'$ of the stream. If $f$ is at end of file, return
the empty sequence. Otherwise read from the operating system (which
may block) until one of those conditions occurs.

$v = \text{inputAll}(f)$
Return the vector $v$ of all the elements of $f$ up to end of stream. Seman-
tically equivalent to:

\[
\text{fun inputAll}(f) = \text{let val } (a, f') = \text{input } f \\
\quad \text{in if size}(a) = 0 \text{ then } a \\
\quad \text{else } a \end{array} \text{ ^ inputAll } f'
\text{end}
\]

where $\end{array} \text{ ^ inputAll } f'$ is the concatenation operator on element vectors.

$(u, f') = \text{inputNoBlock}(f)$
If any non-empty sequence $v$ of $f$ is available or can be read from the
operating system without blocking, return \text{SOME}(w, f') where $w$ is any
non-empty prefix of $v$, and $f'$ is the “rest” of the stream. Otherwise
return \text{NONE}.

$(c, f') = \text{input1}(f)$
If at least one element $e$ of $f$ is available, return \text{SOME}(e, f'). If $f$ is at end
of file, return the \text{NONE}. Otherwise read from the operating system (which
may block) until one of those conditions occurs. Semantically equivalent
to:

\[
\text{fun input1}(f) = \text{let val } (v, f') = \text{input } f \\
\quad \text{in if size}(v) = 0 \text{ then } \text{NONE else } \text{SOME}(\text{sub}(v, 0), f') \\
\quad \text{end}
\]
\( (u, f') = \text{inputN}(f, n) \)

If at least \( n \) elements remain before end of stream, return the first \( n \) elements. Otherwise, return the (possibly empty) sequence of elements remaining before end of stream. Blocks if necessary. (This was the behavior of the \text{input} function in the 1989 \textit{Definition of Standard ML}.) Semantically equivalent to:

\[
\text{fun inputN}(f, 0) = (\text{empty}, f) \\
| \text{inputN}(f, n) = \text{let} \ \text{val} \ (x, f') = \text{input1} f \\
\quad \text{val} \ (s, f'') = \text{inputN}(f, n - 1) \\
\quad \text{in} \ (x \cdot s, f'') \\text{end}
\]

\text{endOfStream}(f)

False if any characters are available in \( f \); true if \( f \) is at end of stream. Otherwise reads (perhaps blocking) until one of these conditions occurs. Exactly equivalent to \((\text{size}(\text{input } f) = 0)\).

\text{getReader}(f)

Extract the underlying \text{reader} from \( f \). Truncates \( f \). Careful users should probably do something like

\[
\text{let} \ \text{val} \ r = \text{getReader } f \\
\text{val} \ v = \text{inputAll} f \\
\text{in} \ ... \text{end}
\]

so as to obtain the elements \( v \) already in the buffer before doing anything with \( r \).

\( f = \text{mkOutstream}(w, s) \)

Create a buffered outstream \( f \) from a writer \( w \). In \( w \), \text{writeBlock}, \text{write-aBlock}, and \text{block} must not all be \text{NONE} or an \text{Io} exception will be raised.

\text{closeOut}(f)

Flush \( f \)’s buffer, terminate \( f \), then close the underlying writer (releasing operating-system resources associated with it).

\text{flushOut}(f)

Flush \( f \)’s buffer: that is, make the underlying file reflect any previous \text{output} operations.
output($f, v$)
Write the sequence $v$ to $f$; this may block until the system is prepared to accept more output. StreamIO does not provide any nonblocking output function.

output1($f, x$)
Write the element $x$ to $f$; may block.

getWriter($f$)
Get the underlying writer associated with $f$. Flushes and terminates $f$.

getPosOut($f$)
Give the current position of $f$ in the underlying file. Not always supported.

endPosOut($f$)
The position at the end of file $f$. Not always supported.

setPosOut($f, i$)
Set the current position of $f$ in the underlying file to $i$. Flush $f$ if necessary.
Not always supported.

Any prefix of the concatenation of previous writes (since the last setPos or flush) may be reflected in the underlying file.

Operations marked Not always supported may fail on some streams or in some instantiations of the STREAM.IO signature, raising Io.

Rules: The following expressions are all guaranteed true, if they complete without exception.

Input is semi-deterministic: input may read any number of elements from $f$ the "first" time, but then it is committed to its choice, and must return the same number of elements on subsequent reads from the same point.

let val (a,_) = input $f$
val (b,_) = input $f$
in a=b
end

Closing a stream just causes the not-yet-determined part of the stream to be empty:

let val (a,f') = input $f$
val _ = closeIn $f$
val (b,_) = input $f$
in a=b andalso endOfFilestream $f'$
end (* must be true *)

Closing a terminated stream is legal and harmless:

(close_in $f$; close_in $f$; true)
If a stream has already been at least partly determined, then input cannot possibly block:

```plaintext
let val a = input f
in case inputNoBlock f
    of SOME a => a=b
    | NONE => false
end (* must be true *)
```

Note that a successful `inputNoBlock` does not imply that more characters remain before end-of-file, just that reading won't block.

A freshly opened stream is still undetermined (no "read" has yet been done on the underlying reader):

```plaintext
let val a = TextIO.openIn name (* or, mkInstream(r), or BinIO.openIn name *)
in close a;
    size(input a) = 0
end
```

This has the useful consequence that if one opens a stream, then extracts the underlying reader, the reader has not yet been advanced in its file.

Closing a stream guarantees that the underlying reader will never again be accessed; so input can't possibly block:

```plaintext
(case (close f;; inputNoBlock f) of SOME _ => true | NONE => false)
```

The `endOfStream` test is equivalent to `input` returning an empty sequence:

```plaintext
let val (a,_) = input f in (size(a)=0) = (endOfStream f) end
```

`getPosIn` is accurate even if two different instreams are created from the same reader and they interleave operations. Thus, the implementation of StreamIO must make no assumption that the position at the end of one `read` operation is the same as the position at the beginning of the next.

**Exceptions** StreamIO functions may raise the `Subscript` exception, if given ill-formed array and bounds arguments by a client; or the `Io` exception. In general, when `Io` is raised as a result of a failure in a lower-level module (PrimIO), the underlying exception is propagated up as the `cause` component of the `Io` exception value. This will usually be a `Subscript`, `SysErr`, or `Fail` exception, but the `StreamIO` module will rarely (perhaps never) need to inspect it.

The components of `Io` are:

**function**

The name of the StreamIO function raising the exception.

**name**

Should equal the `name` component of the reader or writer.
cause

The underlying exception raised by the reader or writer; or Fail if raised on the initiative of StreamIO. Some standard causes are:

- Fail “Random access not supported on this stream” for getPosIn, setPosIn, endPosIn, getPosOut, setPosOut, endPosOut.
- Fail “Blocking writes not supported on this writer” for output, output1, flushOut.
- Fail “Blocking reads not supported on this reader” for input, inputN, input1, etc. inputAll.
- Fail “Nonblocking reads not supported on this reader” for inputNoBlock
- Fail “Operation on terminated stream” for setPosIn.

Unbuffered I/O That is, if chunkSize=1 in the underlying reader, then input operations must be unbuffered:

```
let val f = mkInstream(reader)
  val (a,f') = input(f,n)
  val PrimIO.Rd{chunkSize,...}=getInstream f
  in chunkSize>1 orelse endOfStream f'
end
```

Though input may perform a read(k) operation on the reader (for k ≥ 1), it must immediately return all the elements it receives. However, this does not hold for partly determined instreams:

```
let val f = mkInstream(reader)
  val _ = doInputOperationsOn(f)
  val (a,f') = input(f,n)
  val PrimIO.Rd{chunkSize,...}=getInstream f
  in chunkSize>1 orelse endOfStream f' (* could be false*)
end
```

because in this case, the stream f may have accumulated a history of several responses, and input is required to repeat them one at a time.

Similarly, output operations are unbuffered if chunkSize=1 in the underlying writer. Unbuffered output means that the data has been written to the underlying writer by the time output returns.

Don’t bother the reader input must be done without any operation on the underlying reader, whenever it is possible to do so by using elements from the buffer. This is necessary so that repeated calls to endOfFile will not make repeated system calls.

This rule could be formalized by defining a “monitor.”
val monitor: reader -> {rd: reader, 
charsRead: int ref, 
opCount: int ref}

and making statements such as:

let val {rd,charsRead,opCount} = monitor(reader) 
val f = mkInstream(rd) 
val (f',nElems) = doThingsCountingElements(f) 
val p1 = getPosIn f' 
val c1 = !charsRead 
val ops = !opCount 
val _ = input f' 
in not ((nElems < c1) andalso (!opCount > ops)) end

but perhaps this level of detail is unnecessary.

Multiple end-of-file  In Unix, and perhaps in other operating systems, there is no notion of “end of stream.” Instead, by convention a read system call that returns zero bytes is interpreted to mean end of stream. However, the next read to that stream could return more bytes. This situation would arise if, for example,

- the user hits cntl-D on an interactive tty stream, and then types more characters;
- input reaches the end of a disk file, but then some other process appends more bytes to the file.

Consequently, the following is not guaranteed to be true:

let val z = endOfStream f 
val (a,f') = input f 
val x = endOfStream f' 
in x=z  (* not necessarily true! *) end

The “don’t bother the reader” rule, combined with the definition of endOfStream, guarantees that

delOfStream(f) = endOfStream(f).

Implementors should beware that an empty buffer sometimes means end of stream, and sometimes not; I found an extra boolean variable necessary to keep track.
7 StreamIO

The functor StreamIO layers a buffering system on a primitive IO module:

```haskell
functor StreamIO(structure PrimIO : PRIM_IO
  structure Vec: MONO_VECTOR
  structure Arr: MONO_ARRAY
  val someElem : PrimIO.elem
  sharing type PrimIO.elem = Arr.elem = Vec.elem
  sharing type PrimIO.vector=Arr.vector=Vec.vector
  sharing type PrimIO.array=Arr.array
  sharing type PrimIO.pos=FilePosInt.int
) : STREAM_IO = ...
```

The Vec and Arr structures provide Vector and Array operations for manipulating the vectors and arrays used in PrimIO and StreamIO. The element someElem is used to initialize buffer arrays; any element will do.

The types instream and outstream in the result of the StreamIO functor must be abstract.

If flushOut finds that it can do only a partial write (i.e., writeBlock or a similar function returns a “number of elements written” less than its “n elems” argument) then flushOut must adjust its buffer for the items written and then try again. If the first or any successive write attempt returns zero elements written (or raises an exception) then flushOut raises an io exception.²

Implementation notes:

The previous section gives the specification of StreamIO behavior.

With buffered reading, a getPosIn operation on the instream may be done in the middle of a buffer. Calculating this requires knowing the position of the beginning of the buffer, and using findPos. But this means that the StreamIO system must do a getPos just before reading each new buffer, and remember that position.

Here are some suggestions for efficient performance:

- Operations on the underlying readers and writers (readBlock, etc.) are expected to be expensive (involving a system call, with context switch).

- Small input operations can be done from a buffer; the readBlock or readNoBlock operation of the underlying reader can replenish the buffer when necessary.

- Each reader may provide only a subset of readBlock, readNoBlock, block, canInput, etc. An augmented reader that provides more operations that can be constructed using PrimIO.augmentIn; but it may

²What is the behavior of the StreamIO primitives if a user interrupt occurs? Reppy thinks that losing information is preferable to printing output twice. This should be cogitated and clarified.
be more efficient to use the functions directly provided by the reader, instead of relying on the constructed ones. The same applies to augmented writers.

- Keep the position of the beginning of the buffer on a multiple-of \texttt{chunkSize} boundary, and do \texttt{read} or \texttt{write} operations with a multiple-of-\texttt{chunkSize} number of elements.

- For very large \texttt{inputAll} or \texttt{inputN} operations, it is (somewhat) inefficient to read one \texttt{chunkSize} at a time and then concatenate all the results together. Instead, it is good to try to do the read all in one large system call; that is, \texttt{readBlock(n)}. However, in a typical implementation of \texttt{readBlock} this requires pre-allocating a vector of size \( n \). If the user does \texttt{inputAll()} or \texttt{inputN(maxint)}, either the size of the vector is not known \texttt{a priori} or the allocation of a much-too-large buffer is wasteful. Therefore, for large input operations, query the size of the reader using \texttt{endPos}, subtract the current position, and try to \texttt{read} that much. But one should also keep things rounded to the nearest \texttt{chunkSize}.

- The use of \texttt{endPos} to try to do (large) read operations of just the right size will be inaccurate on translated readers. But this inaccuracy can be tolerated: if the translation is anything close to 1-1, \texttt{endPos} will still provide a very good hint about the order-of-magnitude size of the file.

- Similar suggestions apply to very large \texttt{output} operations. Small outputs go through a buffer; the buffer is written with \texttt{writeBlock}. Very large outputs can be written directly from the argument string using \texttt{writeBlock}.

- A lazy functional instream can (should) be implemented as a sequence of immutable (vector) buffers, each with a mutable ref to the next “thing,” which is either another buffer, the underlying reader, or an indication that the stream has been truncated.

- The \texttt{input} function should return the largest sequence that is most convenient; usually this means “the remaining contents of the current buffer.”

- To support non-blocking input, use \texttt{readNoBlock} if it exists, otherwise do \texttt{canInput} followed (if appropriate) by \texttt{readBlock}.

- To support blocking input, use \texttt{readBlock} if it exists, otherwise do \texttt{readNoBlock} followed (if would block) by \texttt{block} and then another \texttt{readNoBlock}.

- To support lazy functional streams, \texttt{readBlock} and \texttt{readaNoBlock} are not useful; they are included only for completeness.
• **SetPosIn**, if setPos-ing forward, might choose to follow the buffer sequence, and can perhaps satisfy the setPos request without any underlying reader operation.

• **GetPosIn**, in some implementations, can tell the position without a system call, if it knows the position of the beginning of the buffer and the current position within the buffer.

• **writeaBlock** should, if necessary, be synthesized from **writeBlock**, and vice versa. Similarly for **writeNoBlock** and **writeNoBlock**; **readaNoBlock** and **readNoBlock**; **readaBlock** and **readBlock**.

8 **IO functor**

The precise definition of "conventional" streams (**IO** signature) is in terms of "lazy functional" streams (**STREAM_IO**). The functor **IO** is provided:

functor IO(structure S : STREAM_IO) : IO = ...

The structures **BinIO** and **TextIO** are (presumably) built using separate applications of this functor (though **TextIO** is then enhanced with **stdIn**, etc.), but users may apply the **StreamIO** and **IO** functors to make streams data types other than char and byte.

The semantics of **IO** are simple enough that it is sufficient to give a reference implementation.

functor IO(structure S : STREAM_IO) : IO =
let abstraction I =
  struct
    structure StreamIO = S
    type instream = S.instream ref
    type outstream = S.outstream ref
    type elem = S.elem
    type vector = S.vector
    type pos = S.pos
    val mkInstream = ref
    val getInstream = !
    val setInstream = op :=
    val mkOutstream = ref
    val getOutstream = !
    val setOutstream = op :=
    fun endOf f = if S.endOfStream f then f else endOf(#2(S.input f))
  fun closeIn(r as ref f) = (S.closeIn f; r := endOf f)
  fun setPosIn(r as ref f, i) = r := S.setPosIn(f,i)
  val getPosIn = S.getPosIn o !
  val endPosIn = S.endPosIn o !
fun input(r as ref f) = let val (v,f') = S.input f in r := f'; v end
fun inputAll(r as ref f) = let val v = S.inputAll f
  in r := endOf f; v end
fun inputNoBlock(r as ref f) = let val (v,f') = S.inputNoBlock f in r := f'; v end
fun input1(r as ref f) = let val (v,f') = S.input1 f in r := f'; v end
val endOfStream = S.endOfStream o !
fun lookahead(ref f) = #1(S.input1 f)
val closeOut = S.closeOut o !
fun output(ref f, v) = S.output(f,v)
fun output1(ref f, x) = S.output1(f,x)
val getPosOut = S.getPosOut o !
val endPosOut = S.endPosOut o !
fun setPosOut(ref f, i) = S.setPosOut(f,i)
val flushOut = S.flushOut o !
end
in I
end

Note that the *instream* and *outstream* types are abstract.
Some consequences of this definition:
The *endOfStream* semantics are

fun endOfStream (f as ref ff) = StreamIO.endOfStream ff

This implies
let val x = endOfStream f
  val y = endOfStream f
  in x = y (* guaranteed true *)

Furthermore, second call to *endOfStream* is guaranteed not to do any system call; this is a consequence of the “Don’t bother the reader” semantics of StreamIO.input.

However, reading past end of stream is possible via input; the semantics may be straightforwardly derived from the semantics of StreamIO.input.

The output operations (which were not lazy functional to begin with) are even more similar between STREAM.IO and IO. The only purpose of the extra ref in IO is to allow “output redirection.”

9 Application Notes

9.1 Random access reading/writing to the same stream

Instreams are instreams, outstreams are outstreams, and ne’er the twain shall meet. At least, not face to face. However, competent users can construct many things from the layered functors.
Here’s an example: reading and writing to the same random-access file without re-opening it.

1. Open the file for reading, and for writing; extract the underlying reader and writer, discarding the buffering layer.

   ```sml
   val reader = TextIO.StreamIO.getReader
                  (TextIO.getInstream(TextIO.openIn name))
   val writer = TextIO.StreamIO.getWriter
                  (TextIO.getOutstream(TextIO.openOut name))
   ```

2. Do some buffered writes; then discard the buffering layer.

   ```sml
   let val out = TextIO.mkOutstream(TextIO.StreamIO.mkOutstream(writer))
                in TextIO.setPosOut(out,somePos);
                output(out,"Hello ");
                output(out,"World
");
                flushOut out
   end
   ```

3. Do some buffered reads; then discard the buffering layer.

   ```sml
   let val inf = TextIO.mkInstream(TextIO.StreamIO.mkInstream(reader))
                in TextIO.setPosIn(inf,anotherPos);
                input inf;
                input inf
   end
   ```

4. And so on. It’s cheap and easy to do `mkInstream` whenever switching between reading and writing.

### 9.2 Other reader/writer devices

The functions `TextIO.openIn` and `TextIO.openOut` provide system-default ways to create streams (whose underlying readers and writers can be extracted), from “file names.”

SML implementations are likely to provide other ways to create readers and writers. For example,

```
structure Socket :
  sig type socketName
  structure P = TextIO.StreamIO.PrimIO
  val openSocketTextReader: socketName -> P.reader
  val openBidirectionalSocket: socketName ->
                             P.reader * P.writer
   ...
end
```
Then the user could buffer these readers by using `mkInstream`.
Alternatively, a `Socket` interface could provide the high-level `instream`:

```plaintext
structure Socket :
  sig type socketName
    val openSocketTextIn: socketName -> TextIO.instream
    val openBidirectionalSocket: socketName ->
      TextIO.instream * TextIO.outstream
      . . .
end
```

and the user could extract the reader by using `getInstream` and `getReader`.

### 9.3 String readers/writers

A useful kind of reader/writer is an internal text queue, not using any devices at all:

```plaintext
local
  fun primPipe(): TextIO.StreamIO.PrimIO.reader *
    TextIO.StreamIO.PrimIO.writer =
    . . .
  in
  fun pipe(): instream * outstream =
    (* layer mkInstream and mkOutstream on
     components of primPipe() *)
end
```

It would be natural to provide such functions in a library.

Here’s an even simpler example:

```plaintext
fun stringReader(source : string): TextIO.StreamIO.PrimIO.reader =
  let val pos = ref 0
  fun read n = let val p = !pos
    val m = min(n, size source - p)
    in pos := p+m; substring(source,p,m)
  end
Rd{readNoBlock = SOME(fn n => SOME(read n)),
  readaNoBlock = NONE,
  readBlock = SOME(read),
  readaBlock= NONE,
  block = SOME(fn()=>()),
  canInput = SOME(fn()=>true),
  name="<string>",
  chunkSize=size source,
```
close=fn()='()',
getPos=fn()='FilePosInt.fromDefault(!pos),
findPos=fn('{{data,first,nelems},p}=>p+nelems,
setPos=((fn k => if 0<=k andalso k <= size source then pos:=k
            else raise Io{mlOp="setPosition",name="<string>",osOp="",reason="position out of bounds",syserror=OS.noError})
          o FilePosInt.toDefault),
endPos=(fn()='FilePosInt.fromDefault(size source))
end

val openString : string -> instream =
  TextIO.mkInstream o TextIO.StreamIO.mkInstream o stringReader

9.4 Translated readers

Sometimes one wants to apply a translation function to a stream. For example, one might want to translate CR-LF to LF on input, or translated escape-coded ASCII into Unicode. I shall discuss translated input streams (readers) here, but the same ideas apply to translated output streams (writers).

Since anyone is allowed to counterfeit a reader, it is easy to write a translation function on readers:

fun translate1 (source : TextIO.PrimIO.reader) : TextIO.PrimIO.reader
  or
fun translate2 (source : BinIO.PrimIO.reader) : TextIO.PrimIO.reader

Here's an example:

fun remove_CR(rd0 as TextIO.StreamIO.PrimIO.Rd rd) :
  TextIO.StreamIO.PrimIO.reader =
  let fun charCR(#"\013") = ""
       | charCR c = implode c
   fun stringCR s = concat(mapChar charCR (s,0,size s))
   fun option f NONE = NONE
       | option f (SOME x) = SOME(f x)
   fun retranslate(_,0,pos) = pos
       | retranslate(read,nelems,pos) =
         let val s = read nelems
            val len = size s
          fun loop(i,n,p) = if i=s then retranslate(read,n,p)
                          else if n=0 then p
                          else if CharVector.sub(s,i)="#\013"
                          then loop(i+1,n,p)
                          else loop(i+1,n-1,p)
         in loop(0,len,p) end
   in read
   end

in loop(0,nelems,pos)
end

in TextIO.StreamIO.PrimIO.Rd{
  readNoBlock = option (fn get => option stringCR o get)
    (#readNoBlock rd,)
  readaNoBlock = (* etc. *),
  readBlock = option (fn get => stringCR o get) (#readBlock rd),
  readaBlock= (* etc. *),
  block = #block rd,
  canInput = #canInput rd,
  name= #name rd,
  chunkSize= #chunkSize rd,
  close= #close rd,
  startPos=#setPos rd,
  endPos=#endPos rd,
  newPos=#getPos rd,
  findPos=
    case (TextIO.StreamIO.PrimIO.augmentIn rd0)
      of TextIO.StreamIO.PrimIO.Rd{readBlock=SOME readb,...} =>
        fn ({data,first,nelems},pos)=>
          let val p0 = #getPos rd ()
            val p1 = #setPos rd pos;
            retranslate(readb,nelems,pos))
          in #setPos rd p0; p1
        end
        | _ => raise Fail "Cannot findPos"
    end

Note that the positions in this translated reader (and thus in the translated
stream) do not correspond 1–1 to positions in the underlying reader. Thus,
findPos must be implemented. A good, simple solution is to avoid random
access on translated streams:

findPos = fn _ => raise Fail "Cannot findPos"

But here we have chosen to provide findPos whenever possible. Because
the translation is not invertible (we don’t know where the CR characters might
have been), findPos must re-read the original stream.

Users who need to do random access on translated streams might also use a
solution similar to the one in section 9.1: do setPos on the underlying, untrans-
lated reader. Then, after each setPos, apply afresh the translation function
(such as remove_CR) and then apply a new buffer (via mkInstream).
9.5 Abstract positions

In applications where one wants seekable, translated readers with “moded escapes” it is difficult represent positions as integers. This will happen if escape characters semi-permanently change the translation state of a stream, rather than affecting just the next character.

In such a case, one might want to have an abstract data type position, perhaps with a total ordering but without a mapping to integers.

One way to accomplish this is to make a new structure matching the PRIM_IO signature:

```ml
abstraction MyPrimIO : PRIM_IO =
  sig type pos = string (* or whatever *)
  datatype reader = Rd of ....
  ...
end
```

Now one can write translated readers that can deal with translated positions more flexibly, since there’s no 1–1 correspondence property that must be maintained.

The only problem is that the standard StreamIO functor cannot be applied, because the sharing constraint type pos=int is violated.\(^\text{12}\)

The user can write his own buffering functor:

```ml
functor MyStreamIO(structure PrimIO : PRIM_IO ...) (* not sharing type PrimIO.pos=int *)
  ) : STREAM_IO = struct ... end
structure MyIO = MyStreamIO(structure PrimIO = MyPrimIO ...)
```

Now MyIO.instream is a different type than TextIO.StreamIO.instream. If one didn’t rely on pos=int, then one could still make use of the MyIO interface:

```ml
functor MyApplication(IO : STREAM_IO) = struct ... end
```

Also, it is possible to write a function to translate a MyPrimIO.reader into an ordinary PrimIO.reader (but with setPos disabled):

```ml
val NoRandomAccess = Fail "Random access not supported on this stream"

fun standardize (MyPrimIO.Rd rd) =
  TextIO.StreamIO.PrimIO.Rd{
    readNoBlock = #readNoBlock rd,
```

\(^{12}\)The sharing of pos=FilePosInt.int is useful to clients of StreamIO. Perhaps it is not necessary for the internals of the functor. If that were the case, then it would not be necessary to define the functor MyStreamIO, because functor StreamIO could be used. But MyIO would still be incompatible with TextIO.StreamIO.
Lexical analyzers need to process their input efficiently, and often need some amount of lookahead. Line-oriented applications need to read one line of text at a time, efficiently. Both of these applications can make effective use of lazy-stream input.

Consider the implementation of an `inputLine` function, that reads up to the next newline character. A naive implementation would read characters, then concatenate them:

```plaintext
fun inputLine (f: TextIO.instream) =
  let fun loop () = case input1 f
    of SOME(#"\n") => #"\n"
       | SOME c => c :: loop()
       | NONE => nil
  in implode (loop())
end
```

Now, we may wish to avoid all the list construction and `implode` call. Thus:

```plaintext
fun inputLine (f: TextIO.instream) =
  let val g0 = TextIO.getInstream f
    fun loop(i,g) = case input1 g
      of (SOME(#"\n"),_) => i+1
         | (SOME c, g') => loop(i+1,g')
         | (NONE,_) => i
    in TextIO.inputN(loop(0,g0))
  end
```

This has the effect of looking through the input buffer for a newline character, then extracting just the right-length string from the input buffer; but it's all done abstractly.
There are no list constructions, and only one string copy: the extract implied by the \texttt{inputN} call. On the other hand, there is a function call for each character; I do not see this as a problem. We expect ML programs (or, in fact programs in any language) to implement abstract data types via a function-call interface; if this becomes a source of inefficiency, perhaps the solution is for compilers to implement cheaper function calls.

A very similar approach works for lexical analyzers which do more general (perhaps multi-character) lookahead: First scan the lazy stream to determine the length of the token, then use \texttt{inputN} to extract it and advance the stream.

\section{Loose ends}

What about user (and other) interrupts during buffered I/O operations?
